Case 3.—Some of you may have seen this patient before. She was under treatment several months since, in the Presbyterian Hospital, where I removed from the upper portion of the sternum a piece of bone. There was caries of the bone and a small sequestrum in the midst of the carious tissue. You know that sequestra do not usually form in spongy bone. It occurs, for the most part, in the compact tissue of bones, as in the flat bones and the long bones of the extremities. Spongy bones, like the vertebræ, etc., are apt to undergo caries, but you do not often find sequestra there. In this case, however, there was a mass of dead bone, which I removed. I was in hopes the wound would granulate and heal, but the healing process has been very tedious. At present you can see a considerable portion of dead bone in the midst of the spongy tissue. You occasionally see small sequestra like this in the femur, in the advanced stage of morbus coxarius. She is dressing the sore with carbolized oil put on lint. When I did the first operation for the removal of the dead portion of bone I found, on introducing the finger into the opening, that it extended back into the mediastinal space. There was some danger of matter burrowing downward and forming a sinus, but probably the previous inflammation had caused more or less adhesion of the cellular tissue, which prevented any extensive burrowing of matter. It is a situation, of course, in which you cannot very well make a counter-opening; that is, unless there is some very urgent reason for it. It would not be desirable to make an opening down into the mediastinal space unless extreme urgency of the symptoms demanded it. There is some suspicion of syphilis in this case. A great many wives are infected by their husbands without their knowledge, and while we cannot diagnose with any certainty the existence of syphilis here, it is to be suspected. Where there is caries of the bones, as in this case, but no syphilitic eruptions affecting the skin and mucous membranes can be found, we are obliged to remain in some doubt as to the diagnosis of syphilitic disease. It is always safe, however, to make moderately free use of the iodide of potassium, and very often, with advantage also, use the chloride or biniodide of mercury. In doubtful cases, while watching them carefully, it is well to give the patient the benefit of the doubt, and use the remedies which would be likely to give relief if the suspicions were well founded.

Counter-irritation.

Case 4.—This aged gentleman has for some time been troubled with a deep-seated pain in the upper and fore part of the arm. On a previous occasion I cauterized it at a number of points, which caused so much relief that he desires the cautery reapplied at a part where there is still some pain and tenderness on pressure. The cautery which I used on this occasion is one which you see very exceptionally. It was not originated by myself, but by Dr. Thorp, who, on seeing me use a small cautery applied at several points, grouped together a number of short wires, and these, heated to a moderately red heat, enables one, instead of making six different burns, to make six burns at one time. If you heat these to a strong heat you make one large scar by burning the intervening portion of integu ment. But heating it moderately, a number of small scars are made, and for many purposes a cautery used in this manner is preferable to the larger cautery, which is applied by a ball- or wedge-shaped or conical instrument, as the case may be. A person with a moderate degree of firmness can bear the cautery applied in this manner without taking ether. But where the cautery is to be applied to a number of places it is rather a severe ordeal to go through with without an anæsthetic. I have had this applied to myself a number of times, and found it a most effectual means of arresting the gangrenous ten dency at the seat of a furuncle. I heat this and press on it hard enough to make it go through the skin into the subcutaneous tissue. The amount of irritation following it is very moderate indeed. I think, upon the whole, I like the multiple cautery heated upon the spirit lamp very much more than the Paqueline cautery, heated by benzine. For some purposes, however, the latter is to be preferred. You should have the lamp near by, so that the cautery will not cool too greatly while being carried through the air.

Last Saturday I was consulted about a case by one of the attending physicians at the Presbyterian Hospital, the patient having a chronic inflammation over the dorsal surface of the wrist, extending some distance upon the forearm and down upon the hand. There was very great induration and pain. I suggested the use of the actual cautery, and it was applied in a number of places, carried through the skin into the cellular tissue. There has been a very marked improvement in the condition of the patient. He has suffered much less pain; there is less induration than there was, and the prognosis is much better. I think that in almost all cases of chronic inflammation about joints, especially where the inflammation is attended by a great deal of induration of the surrounding tissues, you will find much benefit from this mode of treatment.

The best means of arresting the burning sensation after the application of the heated wire is a strong solution of bicarbonate of soda. It acts like a charm. It is not necessary to apply it longer than the first day, after which an ointment of a drachm of the extract of stramonium to the ounce of vaseline may be used as a dressing. The narcotic effect of the stramonium will act advantageously in relieving the pain at the seat of the cauterization.

There are many medical men who attach no importance to the use of revulsives or counter-irritants, because they do not know how to explain the manner in which they produce their effect in relieving pain or disease. There are some minds so constituted that they will not admit a fact the reason of which they cannot explain. There are many facts, however, which we have to learn by practical experience and observation, and if we cannot go any further than to ascertain the fact that we can produce relief by a certain remedy, not being able to explain the modus operandi, there is no reason why we should not use that remedy. It is desirable we should go further if we can, and explain the modus operandi; we do know the fact, however, that revulsives, whether in the form of sinapisms, or blisters of cantharides, etc., or the actual cautery, do in many instances relieve deep-seated pain and deep-seated morbid processes other than mere pain. The establishment of an irritation upon the surface, immediately above the diseased part, will very often relieve irritations and morbid processes going on at a depth from the surface. There may be a difference of opinion as to the manner in which that effect is produced, but I think you will, in the course of your future experience, find that a very large number of cases are greatly relieved by such remedies. You take one of the simplest cases in which this class of remedies gives relief; a person has a severe pain in the bowels; apply a large mustard plaster over the surface; a burning sensation is produced, and the internal pain, in a large number of cases, is immediately relieved. Of course, if you can get at the seat of the trouble and relieve it by a more radical remedy, which aims at the cause of the pain, it is the better mode of treatment. Very often pain in the bowels, depending on imperfect digestion, for instance, is almost instantaneously relieved by the use of powdered charcoal, or powdered charcoal combined with bicarbonate of soda and some aromatic. In that case the pain is relieved by removing the cause, by neutralizing the acid with an alkali, absorbing the gases with charcoal, and modifying the sensibility of the part by the aromatic. Very often you will be able to relieve a pain of that kind permanently, avoiding the after ill effects of an anodyne, which relieves the pain by blunting sensation of the parts.

Ulcer of the Leg.

Case 5.—This man, about forty-five years of age, has a sore upon the upper and outer part of the leg, which, however, is not apparently connected with the bone; but a number of years past I treated him for disease of the lower part of the thigh bone. He says I removed a small sequestrum of bone at that time. The seat of the disease of the thigh bone in this case is very difficult to get at, on account of the presence there of large blood vessels, namely, in the popliteal space. Sometimes, when the sinus leads directly to the seat of the disease, and the sequestrum is of limited extent, one can get hold of it without much danger to the vessels. There is one serious evil arising from a sequestrum in the popliteal space; that is, where the sequestrum is of considerable size and with a jagged extremity,

it is likely to press directly toward the great vessels. There have been several instances in which fatal hemorrhage came from opening of the popliteal artery by the jagged extremity of a sequestrum pressing against it. This patient is not prepared to undergo an operation to-day.

Case 6.—This patient has a very elongated, ulcerated surface upon the inner side of the leg, which, he says, is the result of a very free incision which was made in the Charity Hospital. I suppose, without showing what the occasion for it was, that he may have had phlegmonous erysipelas, and very free deep incisions are used in that case. It is not very common, however, to make one incision so long as this. It is more common, where there is extensive, deep-seated inflammation and suppuration, to make a number of incisions, which, in the aggregate, would perhaps be as long as this, but leaving intervening integument. This, however, is healing well, and no evil result is to be feared from it. The swelling of the leg has subsided, and all that is required now is to heal the ulcer. I think as good a dressing as he could use for it now is the liquor sodii chlorinati, diluted with eight parts of water. The leg should be raised up on a chair as much as possible.

Anchylosis of Joints.

Case 7.—This boy was brought here some time ago with a stiff elbow, the result of an injury. It was a case of false anchylosis, and by passive motion, the motion of the joint has been restored in some degree. He can lift the hand to the opposite shoulder and to the head. It can be brought to within an angle of twenty or twenty-five degrees of the right line. But there is resistance beyond that point. Now, with regard to the functions of the elbow joint, although it is desirable the patient should have the power of moving the joint in all directions to the full extent, it is very much more desirable that he should have power of full flexion than of full extension. If the elbow joint is even flexed at a right angle, or an angle a little less than a right angle, the patient has command of the most important movements which can be effected. The hand can be brought freely to the mouth and used for almost all purposes required. On the other hand, if the limb be fixed in a straight or nearly straight position, it is very much less useful to the patient. So that in the treatment of affections of the elbow joint you aim more to secure full flexion than full extension. The course to be pursued in this case is to persevere in passive motion, and also in active motion, although the patient complains of the pain thereby occasioned. He may carry a pail full of water, or a heavier weight. Raise it up and carry it, thus tending to draw the limb out into a position approaching the straight one. It is important generally, in the treatment of affections of the joints, to study, with regard to each joint, the functions of its articulation, in order that you may have a definite aim in your treatment. Of course, in all practicable cases you aim to restore all the functions of disabled or diseased joints, but there are many cases in which you will fall short of complete success in that respect. Your aim will be, if the result is likely to be imperfect, to place the limb in a position in which it will be most useful to the patient. Now, with regard to the elbow, the position is one of flexion at a right angle. Anything which you can do beyond that, toward restoring motion in every direction is all very desirable, but if you are obliged to be content with a stiff joint, let it be flexed at about a right angle. If it should be the knee joint that is affected, the position should be one that is straight; a perfectly straight position, or very nearly straight. There is a difference of opinion among surgeons, as to whether an absolutely straight position of the knee, or one very nearly straight, is to be preferred. You may say, at all events, that there is no great harm in having a very slight deviation from the straight position, not more than fifteen degrees. As far as walking on level ground is concerned, a perfectly straight knee gives the patient the best support and the greatest facility for motion; but in sitting and in going up and down stairs, a position that is a little flexed is more advantageous. It depends very much upon what the employment is, and the position in life the patient has, whether it is better to have the knee absolutely straight or deviating a little from the straight line. With regard to the other joints, you have, of course, to study the functions of each. If the shoulder is likely to be stiff, it is better to have the arm by the side of the patient than standing off at right angles; if it be the wrist, it is better to have the hand in the supine than in the prone position. In the prone position it will be much more difficult to overcome the deformity than if it be in the supine position, inasmuch as the pronator muscles are very much stronger than the supinators.

Editorial Department.

Periscope.

Tubercle of the Synovial Sheaths of Tendons.

The *Lancet* says that MM. Terrier and Verchère describe a tubercular disease of the synovial sheaths of tendons, which appears to be more common in the hand than in any other part. The tubercular nature of the affection in the cases they report is demonstrated by the microscopical characters of the inflammatory growth and the concomitance of tubercular disease of the lungs. Premising that the disease may be secondary to tubercular affection of neighboring bones and joints, they draw special attention to the form which occurs primarily in the synovial sheaths. They describe the origin of the affection as insidious, and the progress as very chronic. The first symptom is a swelling over part of a synovial sheath, as, for example, over the palmar surface of a phalanx. This swelling gradually grows and becomes softer; movement of

the part then becomes both painful and limited. Other like swellings appear over other portions of the synovial membrane, as in the palm of the hand and above the wrist. The skin becomes adherent, reddened, and ultimately ulcerates, and pus and sero-pus are discharged; the ulcer extends, its edges being irregular, thin, undermined, and livid. A probe passed to the bottom of the ulcer readily finds a narrow opening into the sheath, along which it may be passed for some distance. The tendons do not slough, nor do they become firmly adherent. The disease does not spread to the neighboring bones and joints; and although in its course more than one part of the synovial membrane is affected, these are separated by quite healthy portions of the membrane, and this fact forms one of the best diagnostic features by which it may be distinguished from fungous disease of the membrane, in which the whole extent of the sheath is always involved. In one of the two cases observed by the authors, there was a very distinct history of an injury as the exciting cause; the patient, a young woman, had cut her wrist severely; and in another case there was a history of a bruise. The constant and rapid movements of the hand are considered to account for the great frequency of the disease there. The only treatment which promises any good seems to be early free removal of the tumors; cases in which this was done with good effect, by Trélat and by Bouilly, are recorded in the paper before us, in the July number of the *Revue de Chirurgie*.

Recovery from Rabies.

The *Lancet* very wisely says:—

On more than one ground the possibility of the recovery of dogs from attacks of rabies is of great importance. The demonstration that this terrible disease is not invariably fatal, even in the animals most prone to it, may at least be welcomed as affording a ray of hope for therapeutics, while the fact of the recovery of affected animals may afford an explanation of many mysterious outbreaks of the disease. M. Decroix lately communicated to the Académie de Médecine nine cases which he had collected, of well authenticated recovery from rabies. (1) M. Ménecier inoculated two dogs and a rabbit with the saliva of a rabid dog; all three died from rabies, but the dog from which the saliva was obtained recovered. (2) Decroix inoculated a dog with the saliva of one suffering from rabies; the latter died, the former became affected with characteristic rabies and recovered. (3) Some saliva was obtained from a man some hours before he died, from hydrophobia, and with it a dog was inoculated; the animal presented well marked symptoms, but recovered. (4) Reg, of Lyons, recorded the recovery of a dog with furious rabies, due to a bite from another rabid animal. (5) A military veterinary surgeon, Laquerrière, has recorded the case of a dog affected in consequence of a bite from an animal unquestionably rabid. The destruction of the dog was ordered, but the owner refused to consent, and the dog recovered without treatment. The four remaining cases were of recovery from rabies, in man in three cases, and in the horse in the last. Decroix points out that in furious rabies the attacks increase in frequency and intensity during two or three days, then attain their maximum, and disappear in two or three days more, whereas death does not occur until the fifth or sixth day. The eminent authorities who have never met with an instance of recovery are scarcely justified in denying the occurrence of such cases described by those practitioners who have seen them. The Rabies Committee, of which M. Decroix was president, has made, since 1874, a host of experiments with various substances of reputed value in rabies, three of them with pilocarpine, and every supposed remedy which they employed appeared actually to hasten death by the violent paroxysms which it caused. The conclusions of M. Decroix are that it is experimentally demonstrated that rabies may terminate in spontaneous recovery. Up to the present day no agent has made good its claim as a remedy for rabies. The cases of recovery attributed to this or that agent may be, with equal justice, ascribed to the spontaneous termination of the disease. The dogs which recovered in the experiments carried on by the committee were left at rest, and, since the administration of medicines usually provokes convulsive seizures, it seems desirable, according to our present knowledge, to leave persons affected with hydrophobia in the most perfect possible calm, trying experiments only upon animals. In absolute quietude and obscurity the paroxysms are far less terrible than when medicines are administered, and M. Decroix asserts that if these conditions could be secured, he would far rather suffer from hydrophobia than from many other diseases. It may, however, be observed that we are scarcely justified in drawing, from the superior results of therapeutic inactivity in dogs, the same lesson in the case of the disease in man. The administration of a drug to the human sufferer by the skin or rectum, or sometimes even by the mouth, may be effected with far less disturbance than in the case of the dog. Without doubt, however, he is correct in insisting on the absolute importance of perfect tranquillity, and of the avoidance of everything which may in any degree help to excite the paroxysms. It may be doubted also whether dogs are the best subjects for therapeutic experiments, since it is probable that the conditions met with in the human subject obtain more closely in the herbivora than in the carnivora. It is very desirable, in the case of any recovery from rabies, that it should be ascertained at what date the saliva ceases to be infectious, and whether the disease can be communicated after the animal has to all appearance recovered. This is a not improbable explanation of the occasional alleged occurrence of the disease from the bite of healthy animals.

Poisonous Effects of Iodoform.

Dr. Henry E. Clark publishes an article on this subject in the Glasgow *Medical Journal*. He reaches the following conclusions: In all the recorded cases there is pyrexia, marked by extreme irregularity, the temperature running up to 104° F., or even more, and falling again very rapidly to near the normal. The rise invariably

takes place in the evening, but the morning fall is nearly always out of proportion to the evening rise. The pulse is exceedingly rapid and feeble, its rapidity being in great measure independent of the rise of temperature. Dr. Sidney Ringer has found that one-fifth of a grain of iodoform would almost arrest the action of the frog's heart. Nausea, vomiting and loss of appetite are invariable symptoms, the vomiting being persistent and very little relieved by treatment. There is always lassitude, headache and dullness of intellect, and often delirium, which in the worst cases passes into unconsciousness, or is followed by localized paralysis. The symptoms sometimes resemble those of acute meningitis, the patient uttering peculiar cries, rolling his eyes, and the headache being intense. Zeissl describes two cases in which there was an eruption on the flexor aspects of the limbs, having the appearance of erythema in the one, but in the other resembling urticaria; the eruption faded in a few days after ceasing the use of the drug. It is curious that although iodoform is so freely used in a great variety of conditions, and in patients of all ages and constitutions, it so seldom happens that constitutional effects are produced, and we are led to ask what are the circumstances which predispose to the absorption into the system, and the production of general symptoms. Mundy holds that the large quantity employed is the chief factor, and speaks of cases where from 2½ oz. to 10 oz. have been applied at one dressing; certainly, in our case, we could not blame ourselves for the reckless employment of the drug, as only five grains were applied each alternate day. Another point, however, to be noted is the condition of surface to which it is applied; thus, on a free surface, where a great deal of the iodoform is carried into or through the dressing by the discharge, the risk of absorption will be less than in a sinus with only one external opening, where the discharge is pent up and the iodoform may be retained for many days. Nor must it be forgotten that some granulating surfaces are more active than others in absorbing materials from without, healing burns being especially adapted for absorption, which may account for the number of fatalities where this drug has been employed in the treatment of burns. These considerations do not, however, account for all the cases of iodoform poisoning, nor can the plausible suggestion of a writer in the *British Medical Journal*, that the action is cumulative, and that poisonous effects are only produced after long treatment, be entertained, in view of the facts detailed as to the case under our observation. We are driven, indeed, however reluctantly, to the position held by Schede, that there is a peculiar idiosyncrasy, rendering certain persons liable to constitutional effects from the local use of iodoform, and that it is therefore necessary, in all instances where it is used, to carefully watch its effects, and cease its use whenever there is a distinct rise of temperature.

—It is stated that no appointment will be made to the chair of Animal Morphology in the University of Cambridge, rendered vacant by the death of Mr. F. M. Balfour.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We welcome an addition to the scientific journals of Philadelphia, in a new venture, "*The Druggists' Journal*, a Monthly Publication of Materia Medica, Chemistry, Botany and Microscopy," published by George A. Frey & Co., 128 S. Third street, and edited by L. E. Sayre, Ph. G. Mr. Sayre is already known, to both medical and pharmaceutical readers, as the author of an excellent treatise on "Organic Materia Medica," and is moreover thoroughly versed in the practical details of his profession. The number before us contains 16 large 8vo pages of reading matter, original and selected, all of solid character. The aim of the "*Druggists' Journal*" will be to publish articles of practical value, to expose impracticable and effete formulas, to aid the student in laboratory work, and to discuss all important questions relating to the policy of the drug trade. The subscription price is $1.50 per year, and we feel confident that no druggist or doctor will waste his money if he remits for it.

——In a pamphlet entitled "An Old System and a new Science," Dr. F. E. Stewart sets forth the reason why, in his opinion, a physician should not prescribe proprietary pharmaceuticals, and also explains the system of "working bulletins," which he believes to be the shortest and most effective plan of getting at the value of a new remedy. Those who would like to read his arguments can obtain the pamphlet gratis by addressing the publisher, Mr. George S. Davis, P. O. Box 641, Detroit, Mich.

——Dr. C. Henri Leonard sends us a copy of his "Multum in Parvo Reference and Dose Book," as edited to date. The price is 30 cents, and it may be had of the author, Detroit, Mich.

——The value of electrolysis in the treatment of stricture of the urethra, seems to be amply demonstrated by the facts set forth in a pamphlet on the subject, by Dr. Robert Newman, of New York. Among hundreds of cases which he has treated he did not have occasion to resort to any other method, and what is more, the results were permanently satisfactory. Copies may be had of the author, 68 West 35th street, New York City.

—The Minister of Public Education, of Russia, has found that the experiment of giving elementary instruction in medicine at the municipal schools of St. Petersburg has been so successful that he has authorized its extension to all the municipal schools throughout the empire.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

VACCINATION AND ITS RESULTS.

From time to time the opposition to vaccination which is always prevalent in the uneducated and superstitious masses, crops out in the more educated, and even in the profession itself. We would not attribute this to deliberate perversity or desire for notoriety. There are minds so constituted that they will adopt an opinion without examination, and then labor earnestly to prove its correctness. Others, again, are impressed by one or two isolated facts, and can only see other facts which give one interpretation to these. Such minds are color-blind as to statistics and high-gravel blind as to logic.

The opponents of vaccination are treated to an excellent article, in *The American*, Sept. 2, from the pen of Dr. HENRY HARTSHORNE, but one the excellence of which they will unwillingly appreciate. He reviews, in a masterly manner, the late anti-vaccination writings of Dr. CHARLES T. PEARCE, P. A. TAYLOR, HENRY BERGH and others, setting forth in a perfectly clear style the unfairness with which they handle statistics, and the baselessness of many of their confident statements.

The results of vaccination are, indeed, so unclear that it is really a psychological puzzle to understand how any person who studies them can harbor an honest doubt as to the benefit of the practice. Dr. HARTSHORNE puts them in a nutshell, in the following comparison of deaths nowadays and in the last century:—

Look at the later statistics of the United States, obtained by our National Board of Health in 1881. Sixty six cities and towns in this country yielded, during that year, in all, 4000 deaths from smallpox. As crowded cities always furnish much the largest number of cases of such diseases, it is not probable that more than a thousand deaths (representing from five to ten thousand cases) occurred outside of the reported cities. Suppose, then, five thousand deaths in more than fifty millions of people. This is one hundred deaths to each million of population. For fear, however, that we have under-estimated the deaths in rural localities, let us add to it, double or treble it—make it, say, *three hundred* to the million living. But, as Dr. Fothergill and Sir Gilbert Blane calculated, upon good evidence, the death-rate from smallpox in Great Britain for thirty years before vaccination was introduced by Jenner, was *three thousand* in every million of the population. Well may it be conceded that the mortality (besides the often hideous disfigurements, blindness and deafness resulting) of smallpox has been lessened since the day of Jenner. Put, again, alongside of the above statements, the almost total absence of smallpox from such a country as Ireland, in some recent years (1866, 1867, 1868, 1869), and the official record in the report of the Massachusetts Board of Health, just issued, of the occurrence of but *two deaths* from smallpox in so large a city as Boston, in eight years—1873 to 1881.

It would take a physician with a singularly elastic conscience to say anything against vaccination after reading the above passage. He must be strangely unaware of the responsibility he incurs, if, in the face of these facts, he throws the weight of his influence against this safeguard.

Indeed, the profession, as such, ought to insist on compulsory vaccination and revaccination every decade of life. The danger has been shown to be null, the protection positive. The duty that, in society, every individual owes to his neighbor is serious enough to justify the State in demanding that he shall submit to this operation as often as the best authorities on the subject pronounce it necessary. As in other matters, if people will not submit to reason, and by

their refusal endanger others, the strong arm of force should be laid upon them.

Personal prejudices are not personal rights, and may be indulged only when they do not compromise the safety of others. Hence we are earnestly in favor of a positive enforcement of vaccination by legal statute in every State in the Union.

THE THREATENED CHOLERA EPIDEMIC.

There has been an uneasy feeling in the United States this summer, that we are on the verge of some serious epidemic. The lateness of the season justifies us now in dismissing these fears, but only for the time being.

In several localities cases with all the symptoms of Asiatic cholera have been reported. One of these, quite lately, was in Michigan, another at Newport, R. I., and they made considerable stir. It is very true that Asiatic cholera is raging with great severity at Manilla; it has been recently at Aden, on the Red Sea; and isolated or sporadic cases are reported at many other places, including those in our own country. It is not unusual here, however, to find severe cases of "cholera morbus" reported as Asiatic cholera, and this may be so in the case of the little boy who died at Newport. If there is anything in the seeming periodicity of Asiatic cholera, it is not due in the vicinity of Philadelphia prior to 1883. The well marked epidemics of that disease in this city, beginning with the memorable infliction of 1832, have been at intervals of about seventeen years—as thus, 1832, 1849, 1866. This seeming periodicity, of course, may be mere accident; but if there is anything in it, 1882 is not a cholera year, while 1883 may well be one.

It behooves the authorities, therefore, to be on their guard, and early next summer to take efficient precautions to prevent the pestilence landing on our shores. This is easier than fighting it after it is here.

In spite of every effort, no satisfactory treatment of cholera has yet been discovered. Its fatality is about the same as ever, and that is very high, especially in the earlier weeks of its outbreak.

Preventive measures, on the other hand, have yielded excellent results. Quarantine and sanitation judiciously, and firmly enforced, have controlled its march with a pleasing certainty. But no tampering with hypothetical objections to them is safe. Isolation, segregation and cleanliness are what are demanded.

The periodicity of epidemics is an established fact, the causes of which were ably set forth by Dr. DeCandolle, of Geneva, in a monograph on the subject, published some years ago. We are not, however, yet in a position to predict their return at given epochs. The vital statistics of the world are far too limited to permit this; but each year yields new facts confirmatory of the theory. Therefore, let us be on the alert for the possibilities of 1883.

CONTRIBUTION TO OUR KNOWELDGE OF THE PERIPHERAL TEMPERATURE OF THE HUMAN BODY.

In his thesis for graduation at the University of Tübingen, Dr. A. Römer has reported at length certain thermometrical observations on the temperature of the human body, made on himself. Of this careful work we find, in the *Centrlbl. f. d. Med. Wissensch*, 1882, No. 46, the following extract, made by Prof. Senator:—

Römer, while living as regularly as possible, first made some observations while holding the instrument in his hand. He found, during the course of the day, far greater variations in the hollow of the hand than in the rectum, where the temperature was taken at the same time. In the former, these variations reached 6.10° C.; in the latter, 1.21° C., only. Notwithstanding outside conditions were the same, sometimes within twenty minutes the temperature in the hollow of the hand varied more than 2°, yes, even 3°, while at other times it continued nearly the same. A carefully kept record resulted in the interesting fact, that there exist certain variations at certain times during the day, but on some days the maxima and minima appeared somewhat earlier and were not quite so great.

The course of the daily curve was found to be about as follows: After the temperature has been comparatively high during the night, in the morning, at 6 o'clock, a rapid fall takes place, reaching its minimum between 9 and 10 o'clock; then a gradual increase takes place, reaching its maximum soon after dinner; between 1 and 3 o'clock, again, a rapid fall ensues, so that from two to three hours later another minimum is reached. Between 6 and 8 o'clock the temperature begins again rapidly to ascend, and only toward morning somewhat slowly declines again. This daily curve of the external temperature is in opposition to the rectal temperature, when compared with the daily medium. The latter shows, from the morning at 8 o'clock, till the evening at 9 o'clock, a higher temperature, but during all the other time of the twenty-four hours a lower one than the medium, while, with a few exceptions, the surface temperature records the opposite. *A rapid fall on the surface corresponds to a rapid increase in the interior, and vice versa*, only during the transitions apparently an exception takes place, and the variations in the hollow of the hand appear about two hours earlier than those in the rectum, and happen once in the day oftener.

Other variations noted, and which have formerly been observed already, are the following: The lifting of the arm causes a slight fall, the dropping of the arm a slight increase of the temperature in the hollow of the hand; impeding the venous or arterial circulation produces a rapid decrease; the same also rapid and severe cooling of even distant parts, as the legs. Digestion seems to have an influence after dinner only, but here a considerable one.

Certainly these variations are caused by the regulation of the heat of the body, according to which an increase of temperature in the interior must, in the healthy body, be compensated immediately by variation of heat on the surface. But this compensation is disturbed in disease; so that the thermometrical record in disease is hardly affected by these observations; but the latter teach us not to consider always even considerable variations as a sure indication of disease; and it may be well to always take, in important cases, the temperature of the rectum, and to make a new number of observations of the human rectal temperature at night, to find out the value of the statement, that even in the earliest prodromic stages of tubercular phthisis the thermometer (on the surface?) shows an increase of at least one degree. If this should be found in the rectum also, and only in such cases, the fact would be of value; but if on the periphery only, then such persons would share this nightly increase of temperature with all healthy human beings.

We further learn from this, with what cautions any so-called diagnostic or pathognomonic sign should be received, and that such sometimes find a totally different explanation, because central experiments were wanting.

CRANIOLOGY OF MURDERERS.

That there is some truth in craniology can alone be seen from the fact that the skulls of the different races are widely different from each other. Drs. Heger and Dallemayne, in Brussels, have now examined the skulls of a large number of murderers, and published the result of their investigations in detail, in the *Annal. de l' Université de Bruxelles*, 1881, p. 1.

It is impossible for us to mention all the numbers of their measurements, and we must be satisfied with giving our readers a few of the more important results of these investigations. They found that most of the murderers have the posterior part of their skulls (and also of their brains) in comparison, more strongly developed than the front part (but without atrophy of the same), that the brain, as a whole, is generally large, and that, therefore, with them, "the intelligence is not strong enough to withstand their strong impulses." Murderers do not form a special, separate class, but they all possess in their brains and skulls an "inequality born with them." Of all the skulls of such individuals, *i. e.*, quasi-professional murderers, who combined with the murder burglary and robbery, or rather, the latter accidentally with the first, this same want of equal development of skull and brain was noted, and in two who had committed more than one such crime, this remarkable unequal development was espe-

cially apparent. Such men with better education, and their animal impulses guided in a different direction, might have become heroes. Violent impulses, if correctly applied, may lead to great deeds, if not to great crimes. We were present at the dissection of Anton Probst, the murderer of the Deering family, and remember to have noted the same large brain and the same preponderance of the posterior part of it.

Notes and Comments.

Hypodermic Injection of Iodoform in Syphilis.

Dr. Ed. Thomann, in Graz, has made a number of experiments to detect the value of hypodermic injections in syphilis, and gives a preliminary statement of the results gained, so far, in an article published in No. 44, 1881, of the *Centrlbl. f. d. Med. Wissenschaften.*

He made use of a solution of 20 parts glycerine and six parts iodoform. He began with 0.30 iodoform and the dose increased to 0.75. He employed also a solution of 0.30 iodoform in 6 ctm. sweet almond oil. He took cases in whom, with decided induration, the inguinal gland had also commenced to enlarge greatly. After he had made ten to twelve injections on different parts of the body, he observed, in all his cases, a gradual disappearance of all signs. He found the experiments of Binz and Högyes confirmed. They had made theirs on animals. The injections produced almost no pain, or very little only, and the local symptoms were very moderate and by no means as severe as those following injections of corrosive sublimate. None of his patients complained of these hypodermic injections of iodoform.

Within two hours the remedy could be demonstrated in the urine. No disturbance of the general health, no increase of temperature or of rapidity of pulse followed, and the breath did not have the odor of iodoform.

The results are undoubtedly such, that they encourage further experiments. The observations were made in the clinic of Prof. Lipp. Should they prove lasting and uniform, we would possess at last a remedy by which we might be able to prevent the poisoning of the system by lues, and the method would be indicated as soon as the slightest induration of an inguinal gland should denote the beginning absorption of the syphilitic material.

A Cerebral Centrum for the Color Sense.

Since it has been found out that many persons are what is now called color blind, the question has been raised, by Dr. J. Samelsohn, in Cologne, if there does not exist a special centre, somewhere in the brain, for the color-sense. In a short, but very well written article in the *Centrlbl. f. d. Med. Wissensch.*, 1882, p. 851, Dr. Samelsohn says, very correctly, that the question might be changed to the following: If there are cases of double-sided hemianopia, in whom the sense for space and light is perfectly intact, while on the respective half-fields of vision the color sense is totally extinguished, Steffen (in *v. Graefe's Arch.* xxvii, 2, p. 6,) has found such a case, and remarks: should there exist one similar case—only one solitary one, but one undoubtedly of the same kind—we would have a clear proof that in the main central organ, the brain, the centre for the sense of space and for the sense of color are divided, no matter how near to each other they may be situated, but there is a special centrum for each of these senses.

Samelsohn now had such a case under his charge, exactly like the one published by Steffen, where, in consequence of an apoplectic seizure, the sense of space and light was perfectly intact, but where the color sense was utterly extinguished. He would have published this case sooner, and mentioned it before Steffen's article appeared, in a meeting of his local medical society, but he hoped to be able to give the result of the post-mortem examination; but under the administration of iodide of potash and electricity absorption was established, all the symptoms disappeared, and then a second seizure—due to an enormous effusion—brought about rapidly the fatal end, leaving the brain in a condition where any attempt at finding this centre, under the complicated morbid process, was utterly out of the question. But the fact has now clinically been established, that there exists somewhere in the brain, a special centrum for the color sense.

Nephrectomy for Strumous Disease of Kidneys.

The following case, recorded in the *British Medical Journal*, by Dr. Thomas Cole, illustrates how inaccurate may oftentimes prove the most painstaking diagnosis: A boy of eighteen was admitted into the hospital with the following symptoms: Micturition necessary every two or three hours by day, less often at night, and pain at end of penis after conclusion of act. Urine below normal density, and contains abundant albumen, blood and pus, but no casts nor crystals.

No renal tumor perceptible. The diagnosis was scrofulous pyelitis. Rest, good food and tonics materially improved his condition. He subsequently became worse, and a slight enlargement of the right kidney could be detected. Growing rapidly worse, it was decided to perform nephrectomy, but on the day before that set for the operation he became much worse and died. At the post-mortem, the right kidney, which was supposed to be the seat of disease, was found only slightly enlarged, containing numerous abscesses but no inflammation of pelvis, while the left kidney (which, in the event of operation, would have been relied on to perform the work of two), consisted only of dilated calices, and had almost disappeared, weighing only one ounce and a half, and measuring two and a half inches in length and one in breadth. It was surrounded by an abscess, which extended down beneath the psoas fascia to Poupart's ligament. Had the operation been performed, it would have been necessarily immediately fatal.

Cystosarcoma Phyllodes.

Dr. C. Friedlænder remarks, in No. 46, 1882, of the *Centralbl. f. d. Med. Wissensch.*, that the cystosarcoma mammæ was first described by Joh. Müller, who mentioned as its special characteristics, that it consisted of papillary excrescences, which could easily be lifted out. Friedlænder then cites a case reported by H. Chiari, in the *Wien. Med. Jahrb.*, 1881, p. 1. A tumor of the size of a walnut was extirpated from the parotid, in several pieces; it had been growing for two years. The pieces were dense, and consisted of a hard, sinew-like tissue on one side, and of a gland-like structure, with fine linear spaces, on the other. Out of these spaces the same papillary excrescences could be lifted, as above mentioned. After a microscopical examination Chiari pronounced the tumor to be an adenomyxoma. Three weeks after the operation the patient died, of erysipelas. At the post-mortem several metastatic nodules, up to the size of a walnut, were found in the lungs. They presented, under the microscope, the same histological structure as the tumor of the parotid.

Curare in Epilepsy.

Dr. Kunze highly recommends this powerful substance in the treatment of epilepsy (*Journ. de Therap.*). He obtained nine perfect cures in thirty-five cases. The facts reported by him prove that even at advanced stages of the disease, when the intelligence is somewhat affected, complete cure is sometimes obtained and partial return of the intellectual faculties ensues.

Edelfren, encouraged by these observations, has given curare in confirmed cases, for the bromides, associated or not with atropia, are not always successful. He adopts the following prescription of Kunze:—

℞.	Curare,	grs. viiss	
	Aquæ destill.,	℥j–ɱxx	
	Ac. muriatic.,	gtt. j.	M.

He injects, once every five days, about ten minims of this solution. In his hands the hypodermic injection has never been followed by inflammation or any toxic symptoms.

Locomotor Ataxy, of Syphilitic Origin.

When M. Vulpian asserted that almost one-half (40 per cent.) of the cases of locomotor ataxy were of syphilitic origin the proportion was considered to be much exaggerated; but since that period the researches and observations of M. Fournier have demonstrated that M. Vulpian's affirmation was correct, and that the proportion given was rather under than above the actual number of cases. According to M. Fournier, in almost all cases syphilis has a part in the production of locomotor ataxy, and he gives the following rules regarding the management of the case: 1st. Always seek for any manifestations of syphilis in cases of locomotor ataxy. 2d. If such exist institute immediately prolonged and severe anti-syphilitic treatment. 3d. Syphilis should be energetically treated from the début, so as to prevent the occurrence of such serious accidents later on.

Iodoform in Tuberculous Pharyngitis.

At a recent meeting of the Soc. Médic. des Hôpitaux, M. Gouguenheim related the facts of a case of tuberculous ulceration of the pharnyx cured by applications of iodoform. The different forms of tuberculous angina, well described by M. Isambert, were considered by him as fatal. In M. Gouguenheim's observations, applications of iodoform very rapidly induced cures of the ulcerations; it is true they recurred twice, but at present they seem to have definitively disappeared. M. Gouguenheim employs a solution of iodoform in ether, but insufflations of the powdered drug may be directly used on the ulcerations. He concludes, from his observations, that iodoform is a powerful modifying agent when applied to tuberculous ulcerations.

Iron in the Urine.

It is well known that muriatic acid, when added to urine, causes a dark brown-colored uric acid to be set free. Dr. Kunkel (*Würzburger Phys. Med. Ges.*, 1881, *A.*) has detected that the coloring matter contains iron. But not all the iron is removed in this manner out of the urine, even not if urate of sodium and acid are added repeatedly.

Kunkel was able, also, to get out of melanotic tumors a black coloring matter containing iron. He extracted the finely powdered substance and precipitated the solution with muriatic acid. Salkowski supposes that the iron was connected with impure albumen.

A Gall Bladder of Enormous Size.

The following interesting and perhaps unique case is described by Dr. B. Stiller in the *Pester Med.-Chirurg. Presse*, 1882, No. 38 :—

A woman, aged 64, presented a tumor which, beginning at the right axillary line and extending diagonally toward the middle line of the abdomen, reached as far down almost as the symphisis pubis. This immense swelling was found to be an enlargement of the gall bladder. Stiller detected, at the post-mortem examination, that on the lower surface of the liver a carcinoma had grown, which compressed the ductus choledochus, causing this undoubtedly unique enlargement.

News and Miscellany.

British Medical Association—Meetings of Sections.

SECTION OF PUBLIC MEDICINE.

The address in this Section was delivered by Dr. Alfred Carpenter. He contended that a large portion of the rapid growth of the British Medical Association has come to pass because its foundation was intimately associated with inquiry into the causation and prevention of disease, and the application of the principles which regulate the health of the general public. When our founder put forth his programme there was no general Association for the furtherance of these objects, which, to my mind, have revolutionized the system of medicine. The prospectus which he published in 1832, put forth, as a *raison d'etre*, "The investigation of the modifications of endemic and epidemic diseases in different situations, so as to trace their connection with peculiarities of soil and climate, or with localities, habits and occupations of the people." I claim the object which is stated in this paragraph, in his prospectus, as the principal lever by which the success of his movement has been achieved. The whole of the five points contained in his syllabus could only be obtained by a combination of persons, and the mutual support which observers over large areas could afford ; but not one equaled in importance that which is now known as the science of preventive medicine, and which is contained in two of the five points advocated by Sir Charles Hastings. We may, therefore, fairly assume that the benefits which the British Medical Association has been instrumental in producing have been enormously enhanced by this part of our founder's programme ; and that, of the five points of his syllabus, those connected with preventive medicine held, and will continue to hold, the most important place, because they are bonds which are most capable of uniting us together in a general brotherhood for one common beneficial and unselfish object, while they unite us most directly with the public at large, for it is the only Section to which, at its meetings, the outside public are admitted.

I propose, with your permission, to review very shortly the sanitary work which has been directly performed by the Association.

In the first volume of *Transactions* there are some valuable observations upon the objects and modes of medical investigation, by Dr. Barlow, of Bath, and with it is a proposal by Dr. J. Conolly, of Warwick, to establish County Natural History Societies, for ascertaining in all localities what states are productive of disease or conducive to health ; thus connecting our own particular work with the objects and transactions of the Association. There is also a valuable report upon the state of disease in the city of Worcester during the year 1832, by Dr. R. N. Streeten, of this city.

The second volume contains papers upon the "Variations in the production of certain diseases not usually supposed subject to epidemic influence," and upon cholera. In the third volume are observations upon cholera as it occurred in Bristol.

In the fifth volume appears an article on "Glanders in the Human Subject," by Dr. James Johnston. The writer does not allege that he was the first to draw attention to the subject, for he refers to cases published by Mr. Travers, Dr. Elliotson, Mr. Massey of Nottingham, and others on the continent, but he says that the materials at hand were scanty. He connects the cases with farcy, and points out its likeness to gonorrhœa and syphilis, and draws attention to the effect upon human beings of matter from animals, which at that time was supposed to be unlikely to happen, the opinion of most physiologists being that there was an absolute barrier between the two classes of creatures, notwithstanding the evidence afforded by Ceely's observations. It was a good work, associating disease in man with its factor in the animal kingdom, so as to bring that connection forcibly to our notice, and to popularize the idea in the minds of the profession. It has helped to bring forth important fruit. The same volume contains a masterly report upon the then condition of medical relief for sick paupers, by the Messrs. Rumsey and Robert Ceely, which, with a paper by Dr. J. Yellowley, addressed to Lord John Russell, was greatly instrumental in drawing attention to the terrible evils under which at that time the poor of the land were placed by the local authorities,

and to the serfdom under which medical men labored, who were appointed to attend upon the poor. This serfdom could not, but for our Association, have been fully exposed to public view. In those days, there were no local newspapers to ventilate the grievances of the oppressed local doctor. The medical press had a very limited influence, and was seldom read by others than a small body of medical men, who were without any kind of political power; for which reason, time serving politicians scarcely cared to trouble themselves with us and our complaints.

In the sixth volume is a report upon "Influenza or Epidemic Catarrh," which appeared so mysteriously in the winter of 1836–7, and, but for the Association, would have left very little record of its infliction. The Council issued a circular to the members, requesting information as to the origin, progress and duration of the epidemic; the atmospheric phenomena preceding and attending it. A most elaborate report occupying sixty-seven pages of the sixth volume, was drawn up on these answers. A chart with dotted and shaded lines shows the apparent alliance between the fall of temperature and the rise of influenza; but the supposed influences are shown to be checked, by evidence obtained from many parts of the country; they did not stand in the relation of cause and effect, for the conditions were present in some places, but were not accompanied by the influenza. The consideration of the condition of the public health occupied an important position in the proceedings, for the following resolutions were adopted at the annual meeting at Cheltenham, in 1837:—

1. That it appears desirable to this meeting that the members of the Association, in their several localities, should urge upon the members of legislature the importance of an enlightened consideration of the question touching public health, now pending in Parliament.

2. That the meeting suggests to the members generally the propriety of lending their aid to carry into effect the Act which has recently passed the legislature, to produce an improved registration of births, deaths, and fatal disease.

3. That, as the Association feels persuaded that an extensive series of observations, made in the various sanitary institutions of the kingdom, would contribute especially to the progress of medical science, a committee be appointed to draw up tabular forms for statistical records of disease.

The address on "Medicine," before the Association, read by Dr. Malden, in 1838, dealt largely with the questions of causation and prevention, and a large portion of the *Transactions* of this year is devoted to Medical Topography. The meeting held in Liverpool, in 1839, is noted for the attention given to hygiene. The president dwelt very forcibly upon public health, remarking, "We have to consider various and important subjects; one of them is that of hygiene, a study in this country, comparatively overlooked; surely it must be considered no small part of the duty of a medical man to preserve health, as well as to combat disease, and this can only be done by vigilantly observing and making known local circumstances which lead to it.

A Public Medicine Section was first organized at the Oxford meeting, in 1868, and has been regularly instituted since that date. In 1875 I had the distinguished honor of reading an address upon Public Medicine, a position which that subject occupied for the first time at the Sheffield meeting.

The impetus given to original research by the Scientific Grants Committee, the foundation of the Hastings medal, the registration of disease, as suggested by my distinguished predecessor in this chair, Dr. Ransome, and especially the establishment of examinations in subjects relating to public health at our Universities, have tended to help forward the good work. The latter is especially due to the enlightened men who have acted as your guides upon the Committee of Council, assisted by those who have been placed at the head of the staff of the *British Medical Journal*. The position that sanitary science and preventive medicine now occupies in the estimation of the public is due, in a great measure, to the steps which Sir Charles Hastings took when he founded the Association, fifty years ago; and in his honor, as well as for the public good, I ask you to assist to render it all that can be desired that it should become. Time would fail me to refer to all the works connected with our subject; but with an able editor of our journal, especially devoted to hygiene, and who lets no opportunity slip of promoting those objects which especially belong to our branch of the Association work, there must be a great future in store for us; and the revolution in medicine which a study of prevention is likely to effect may be nearer than most of us suppose to be the case. Our successors in this work, who will occupy our places fifty years hence, will then, perhaps, be able to give a tribute to our memory, not on a par with that which we wish to bestow upon our founders, but one which will tell to future generations that we have not been false to the trust which we have undertaken to perform.

SECTION OF OPHTHALMOLOGY.

The address in this Section was delivered by Dr. James Vose Solomon. Contributions to Ophthalmology used to constitute a part of the proceedings of the Section of Surgery, and it was not until 1880 that a separate section was created. In June of that year the Ophthalmological Society of the United Kingdom was founded. At the recent International Medical Congress it was stated by Dr. Horner that he had reduced, by the employment of antiseptics, his cases of suppuration after the operation for cataract, to a fraction over one per cent. as compared with six per cent. I assume that to have obtained such satisfactory results special care must have been taken to exclude patients suffering from diabetes, renal degenerative changes, or advanced atheroma. When we have doubts of the patient's reparative powers to heal the incision by primary union, Dessmarre's operation of sub-conjunctival extraction, with the modern improvements as to length of corneal incision and treatment of the iris, is well worthy of adoption. In a case of diabetic cataract I have lately had recourse to reclination, and obtained a good result as to vision. The steps of the operation are facilitated and obtain greater precision by the employment of two

needles; one being passed through the cornea, in order to press the lens back to a sufficient distance from the iris to allow of the scleral instrument being brought in front of the lens without entanglement in its capsule or the iritic structure. At the Birmingham Eye Hospital the extractions are dressed with pads of absorbent cotton-wool, medicated by boracic acid. Suppuration of the flap after a cataract operation has been sometimes traced to dietetic poverty.

There is an exceedingly rare complication of hard cataract which deserves notice, and in which extraction affords success. We have no indication of its presence until we are in the act of making our flap, when we are surprised to find that the aqueous humor continues to flow, in freedom and quantity quite unusual, and also that the sclera presents wrinkles before the section is finished, and when completed we have before us a collapsed bag, the cataract lying far back. I have operated in two cases, one of whom was a female dwarf, the other, a male fifty-four years of age; recovery took place without a bad symptom, and the vision was good for the reading and correspondence required in a large business.

Of late, the subjects of intra-ocular tension and glaucoma have excited renewed attention in respect to the changes of position and structure of some of the parts that are concerned in effecting the normal filtration of the intra-ocular fluids, and especially to the surgical methods best adapted for the relief of various phases of the glaucomatous process. A new operation will be described to us by Dr. Grossman.

It is just twenty years ago since I combated the then prevalent dictum that all cases of excess of tension necessitated an iridectomy, and declared that my experience justified me in asserting that the recurrence of tension after an iridectomy performed for the relief of chronic or subacute glaucoma "may generally be completely overcome without resorting to a second or third iridectomy, as advised by Von Gräfe.

There are some other subjects to be brought before us, which, were it not that the present epoch has been endowed with the immortal discovery of the ophthalmoscope by Helmholtz, would have been impossible of elucidation. Mr. Nettleship will open a discussion on the question, To what extent do the signs derived from the examination of the eye and its appendages contribute to the localization of central nervous diseases? Dr. Gowers and other eminent brethren are expected to take part in the discussion. The application of the ophthalmoscope to the diagnosis and treatment of errors of refraction will be treated in a paper by Mr. Juler. Mr. Priestly Smith has a new perimeter to show, and, for discussion, a curiously interesting medical case.

Gentlemen, I have detained you too long, and wearied you, I fear. Let me assure you that I would gladly have spared you these pains had not that obdurate and cruel tyrant, precedent, dominated and enslaved me. I have, I confess, not altogether unwittingly followed it; for the position I now occupy, by the favor of my brethren, only falls once in a lifetime to the lot of any of us. I am old enough, as many of us are—so rapid has been the advance—to remember ophthalmic surgery as taught by Lawrence, Tyrrel, Mackenzie and Guthrie. How obscure did they leave much of the *rationale* of many eye diseases; how helpless and imperfect much of their treatment! Minute anatomy, physics, and applied mathematics have changed all that. We can now retort to those who sneer at the varieties of medicine by pointing to our little domain, the privileged home of an almost exact science. That it is so, the labors of this Section will, I feel certain, help to prove; and to that demonstration, gentlemen, I cordially invite you.

SECTION OF OTOLOGY.

The address was delivered by Dr. W. Lairdlaw Purves, who said that, as far as known methods of examination go, we have embraced every one which can assist us in the determination of structural change. The auricle, the meatus, the membrana tympani, the tympanic cavity to a certain extent, with the naso pharyngeal cavity and the Eustachian tube, are all under observation as exact as any part of the body. By the use of mirrors, of microscopes, and of specula, we have within the last few years been able to determine changes of the structure, of the position, and of the mobility of those organs which were before a sealed book. By the use of auscultation, bougies, and currents, we determine the existence of extravasations, the patency of tubes, the alterations in equilibrium. But beyond these the actual demonstration of the integrity or impairment of structure has not arrived.

For the purpose of exactly determining abnormal changes of function, it is necessary that we should have some standards of the normal power. In this respect we are deficient. The determinations at which we should strive to arrive may be classed as those which ascertain. We require tables giving us the results of determinations of acuteness of hearing at certain ages, for fluctuating conditions of atmosphere, for different dimensions of rooms in which the observations are made, for conditions of the body at the time, as to general, muscular, nervous or circulatory states, apart from localized aural conditions. We have not any satisfactory instrument for judging the power of the voice, which would give us the best and most useful of all tests. Nor have we a ready plan of ascertaining the exact amplitude of fork-vibrations to which the nerve does not respond. The determination of the field of audition claims attention. The range of audition, *i. e.*, the range of vibrating pitch determinable by the patient under the same conditions. This sense corresponds to color perception, and if its further study will give us results corresponding to those obtained by the abnormalities of color perception in various general nervous affections, it would add to the exactitude of the diagnosis of those obscure diseases.

The power of judging the direction of sounds is, perhaps, not one of much importance in a civilized state, but it is a subject of interest and worthy of research.

For practical purposes, the recognition of timbre and the duration of impression do not call so much on our attention as the accommodation of the ear. This has, as yet, as far as I know,

baffled determination, and yet it is one of the most common complaints of weakness and age. When arising from a general condition, such as anæmia or diphtheria, we have a clue as to its extent by determining the loss of accommodation from which the sister organ suffers; but, in cases of local change, apart from general loss, I know of no standard.

These embrace the principal tests which should be made in the healthy, from which we could make deductions as to functional changes. We have a mass of information upon some of these points, while on others our knowledge is meagre. Some of these examinations may seem superfluous, and lead us at present to no apparent practical profit to those claiming our aid. Let us remember how seemingly disjointed fragments of physical science, collected by workers with different aims, every now and again receive, by one fresh ray of light being thrown on the whole, a new and general connection and bearing to each other, verifying the belief that all observations of an exact kind will certainly be turned to account some day, and often when least expected.

Are our therapeutical means in a more satisfactory state than our methods of diagnosis? As far as operative interference goes, they will, I believe, compare favorably with any branch of surgery. The results of manipulative interference on the membranes, the throat, the tubes, the cavities, are often marvelous. When we call to mind the benefits derived from restoring tension, removing obstructions, dilating tubes, renewing equilibrium, altering the position of pressure, or varying the calibre of the resonator, we may rest assured that the knowledge and proper application of these operations will give succor to those in need, and satisfaction to ourselves.

There is one agency which ought, I think, to be more carefully cultivated than it is at present, and that is, electricity. Seemingly of no benefit in the majority of cases in which it has been used by me as a therapeutical power, cases now and again arise in which the benefit rendered has been great. With such cases before us we should not despair of being able shortly to diagnose the cases in which it is of service, and prescribe it with gratifying effect.

Failing in curative means, we turn to artificial aids, to the conduction, collection, or magnifying of the motions perceptible by the ear. The name and form of these is legion, and yet they come. The utility of what we have hitherto employed has been great, but I have no hesitation in saying that the application of the discoveries of the last few years will shortly develop aids to the deaf which will far outshine the advantages hitherto afforded by those in common use. Remembering that, even with the absolute destruction of the external and middle ears as a functional apparatus, we have other highways by which we can arouse the acoustic nerve to sonorous vibrations, and recollecting that we have now methods of magnifying these, of collecting them, of producing different tensions, and of vibrating membranes, as shown by microphones, resonators, and telephones, I trust the day is not far distant in which a healthy acoustic, and even a somewhat degenerated one, can be supplied with apparatus which will make it almost independent of the natural conducting apparatus of the ear. Nor do my hopes flag here. To that being who claims our pity beyond even those who seek our aid, who has but one avenue to the soul unclosed, the loss of which would cause a moral death, to the deaf-mute, I believe there is hope. Seeing the strides which our knowledge of vibrations is making daily, and the astounding results obtained thereby, I see every reason to hope that some method of amplifying and rendering such vibrations visible to the eye may be devised, which may render his intercourse with his fellow-beings easy and profitable.

Looking, then, around at what has been achieved in our specialty, and taking that as an earnest of the advantages which we are able to dispense to suffering humanity, I invite you to the discussion of the subjects prescribed by the Executive Committee: trusting, by the collection and comparison of the experiences of members, to forward each other in assisting to place the distressed, not only in a condition free from physical torment, but in a position by which intellectual culture and recreation can only be attained.

SECTION OF PATHOLOGY.

The address in this Section was delivered by Dr. J. Hughlings Jackson, who commenced by stating that "Pathology is the basis of every rational system of therapeutics." To those who are quietly and laboriously working at what may, superficially looked on, seem to be obscure pathological problems, steady advances in diagnosis and rational therapeutics will be chiefly owing. It is evident that, for rational therapeutics, we must know what there is to be treated. No man in our profession deserves greater credit than the pathologist—including, of course, the clinical pathologist, and never forgetting the medical officer of health. The medical officer of health is the pathologist of the social organism, and deserves the highest social recognition. Speaking more narrowly, tacitly assuming the obvious qualifications, the best practitioner, perhaps not the most confident one, is he who has carefully made most post-mortem examinations. I do not mean him who stops here, who stops in a stage which is rather to be called one of morbid anatomy than of pathology. But a man must begin here; must begin here to learn for himself, at any rate. The only way of being thoroughly practical is to face the facts, to get verification or disproof of our opinions. A post-mortem examination never flatters us. If, for an example, we diagnose tumor of the cerebellum during the life of a patient, we may, post-mortem, find one in the anterior cerebral lobe. Such a rap on the knuckles is good for us. It makes us less confident, and teaches us to be more careful. A post-mortem examination may tell us that we have been treating a patient with useless, perhaps with injurious, drugs.

Besides scientific pathology there is a crude pathology, and there is, unfortunately, a metaphysical pathology. We have long heard that old maids' husbands are always well behaved, and on the same principle the pathology of those who do not make post-mortem examinations is often confident and definite. He who has made

many post-mortem examinations is not so metaphysical in his explanations of the pathology of some of those cases of disease of which there is no known morbid anatomy. In looking carefully for himself into the coarsely concrete, a realistic habit of mind is produced in a person, and thus he avoids verbal explanations of those most difficult cases which are without known morbid anatomy—of those, for example, commonly called the neuroses. To my young hearers I say, always endeavor to obtain post-mortem examinations. If a man do not learn pathology when he is young, he is not likely to learn it properly later. I would urge on young medical men the formation of clubs for making post-mortem examinations. Let me mention a slender personal experience. Many years ago, at York, a club of this sort was formed. It had no other organization than the agreement that each member should obtain an examination whenever possible, and ask the other members to attend. The history was stated by the person who, so to speak, owned the case, and then each of us saw what there was to be seen, and notes were taken. In this way it is not difficult to get a large experience of direct value for practice.

Coroners' cases are important, not only for the sake of knowledge, but for discipline. A man has to bring his thoughts quickly to a focus. A collection of good reports on these cases would be very valuable for many practical purposes. I do not suppose that our editor has any space to spare, or I would suggest a department in the *Journal* for brief reports of coroners' cases.

A practitioner must not be a pathologist only, although, unless he be a pathologist, he cannot be a good practitioner. Division of labor, strictly or figuratively, is the law of everything whatever. Some of us work chiefly at physiology, some of us at pathology, and some of us at clinical medicine. But to be a good practitioner, a man must know much of all three, and most of us nowadays carry on the three lines of investigation. Every case is a departure from healthy states, and no one is fitted to begin the scientific study of diseased persons unless he know much of the anatomy and physiology of healthy people. To a great extent diseases are, metaphorically speaking, experiments, anatomical and physiological, on the human body. If it be not profane to say so, I would suggest that anatomists and physiologists might have more recourse to these "experiments." Charcot, in doing the best kind of pathological work, has, I should suppose, done as much for the anatomy and physiology of the spinal cord as any one living. He is clinical all round. The three things make up the clinical problem. I do not mean that we have simply to draw incidentally on our anatomical and physiological knowledge when we see a patient, but that anatomy and physiology are integral parts of every case we have to do with.

When we stand at the bedside of a patient, when we come close to our clinical work, there is before us an anatomical, a physiological, and a pathological problem. A great part of our clinical knowledge of cases is really nothing more than anatomical and physiological knowledge. The word disease is too vague; it is used in three senses, each of which should be individualized. Since I am about to speak of cases of disease, it is not needful to add, were it correct to do so, the adjective morbid to the terms anatomy and physiology. I can best illustrate by diseases of the nervous system.

In each case: 1. There is alteration of structure of some organ; here is an anatomical problem. 2. There is alteration in the proper functional activity of that organ; here is a physiological problem. 3. There is a change in nutrition of tissues of that organ; here is a pathological problem. In many cases we cannot carry out this threefold scheme. But we should attempt it in every one, in order that we may realize vividly what it is we do *not* know. There is a wider pathology than abnormal nutritive changes in one organ. There is not only the organ diseased or most diseased; there is also the rest of the patient to whom that organ belongs or did belong. I say, "or did belong," because sometimes part of an organ is annihilated. No clinically minded man ever forgets the wider pathology. We no longer believe that a patient "is attacked by disease," although we still use that expression, the metaphysics having long since died out of it. It would be better metaphor to say that the patient breeds the local disease himself, or that it has grown out of the whole of him; or, better still, to say, of many cases, that a certain part of a universally unsound system has fallen to pieces. So we examine our patient all over; we try to get to know as much as we can of the pathology of all important organs of the living patient.

Even yet our pathology is not wide enough. We must not consider the patient himself as more than a detached unit of his family; we have to note the tendencies he inherits, as well as to examine him to see how they are particularly evidenced in one branch or twig of a family tree.

If we take a case of a loss of speech, the threefold distinction in clinical investigation can be easily illustrated. To locate the lesion is nothing other than an anatomical conclusion. To ascertain that it has destroyed speech, that it has left the patient capable of understanding what is said to him, etc., is a physiological (and psychological) investigation. Pathology is concerned only with the nature of the lesion and with its mode of production. Nearly all that has been written on aphasia is anatomical, physiological and psychological disquisition.

To take a still more simple case in illustration; a man has hemiplegia. To think of the case as one of paralysis only, is like the habit of thought of old-fashioned zoölogists, who spoke of animals as if they had nothing particular inside of them, or, as Forbes said, as if they were skins stuffed with straw. We have three very different things to do, each easily done in most cases of this kind. From noting the region affected—face, tongue, arm, leg, etc.—we conclude that there is a lesion of the opposite corpus striatum. Now, this is only anatomical knowledge. Speaking figuratively, it is only an experiment made by disease on an organ. To locate disease is an admirable thing; but localization is not the most important clinical thing. If we stop in this stage, we know nothing of any value for rational treatment of the patient; we may have some good empirical expedients. Next, observing that the

region mentioned is paralyzed, we conclude that there is loss of function of some nerve elements, probably destruction of them. This—physiology—also is a knowledge by itself, of no avail for therapeutical purposes in such a case. But, lastly, by examining our patient all over, for now we have done, for the time, with his paralysis, and from certain empirical evidence, not needing to be stated now, we conclude that loss of function of the organ is caused by cerebral hemorrhage, that a clot has smashed up part of the corpus striatum. This is not enough. There is yet the wider pathology. A patient looks on this illness as an accident; the pathologist never takes that view of it. We often get to know with certainty that the local pathological change is but a local manifestation of a slowly progressing wide state of degeneration; that the man is rotten all over, and that he has one day broken down suddenly in a certain place; that he has chronic Bright's disease, atheromatous arteries, and an hypertrophied left ventricle. By considering these things and their inter-action, we see that he has long been preparing for what seems to him to be only an accident. I submit, that the process by which, in such a pathological state, he comes to have the local lesion—why an artery bursts—is, in chief part, a physiological problem; there is a physiology of the organism made up of bad materials as well as of the healthy organism. Further widening our pathological investigation, we may find that the patient is a twig of a gouty family tree.

Now, the pathology of lesions is the basis for treatment. The best illustration of indirectness of pathology is given by that most important clinical group of cases, syphilitic affections of the nervous system. Without denying that syphilis may primarily affect nerve-tissue, what I only feel sure of is, that it begins in subordinate tissues of nervous organs. The most nearly direct method of "attack," if I may use the word, is when a nerve trunk is the seat of syphilitic disease: but in other cases the process is indirect. Thus the commonest kind of so-called syphilitic hemiplegia depends directly on local softening of the brain, and indirectly on syphilis. This is an excellent illustration, showing how pathology gives precision to therapeutics. What a man has really to treat, if he is trying to cure a patient of syphilitic hemiplegia of this kind, is "local softening of the brain," not syphilis. The order is this: a man has a chancre; he gets rid of it and of subsequent secondary symptoms. Months or years later, when apparently well, except perhaps for headache, some of his cerebral arteries are becoming syphilitically diseased, and then one unfortunate day a branch is blocked up and he becomes hemiplegic. A very little change happens that day, although the consequences are grave; but for that little seeming accident there has been long, slow, insidious preparation. The syphilis is slow, the thrombosis is rapid. This case for treatment, so far as the hemiplegia is concerned, is as certainly one of local softening of the brain, as hemiplegia from ordinary embolism is. To call it syphilitic hemiplegia is all very well, but to think of the paralysis as being a direct result of syphilis is crude pathology.

Next, as to therapeutics. Suppose the patient recovers rapidly under iodide of potassium, should we say we had cured him? There are the facts that he is syphilitic, that he took the iodide, and is now well again. No one denies this sequence. But, then, it so happens that there is another fact. It is quite certain that some hemiplegic patients get well without any drugs whatever. Whether a patient recovers from hemiplegia or not is a question of the size of the lesion. Those who make *post-mortem* examinations do not invoke shrinking or disintegration of the plug, or re establishment of collateral circulation, because they know that they find holes in the motor tracts of patients who have recovered from hemiplegia—the patients got well, were not cured. So that the hypothesis that the iodide cured the patient is not warranted by facts. Of course, we should treat the patient for syphilis, for, besides more obvious reasons, there is the strongest presumption that other cerebral arteries are diseased, and we may rid them of disease. If the paralysis be transitory, we go on treating the patient for syphilis, to prevent further paralysis. Everybody has a well-grounded faith in the treatment of syphilis—or of its recent effects, at any rate. But I submit that if we could sweep away every vestige of syphilis by drugs, we should not, by so doing, cure the hemiplegia. It is easy to let ignorance stand to us for knowledge. We may believe we have cured our patient by drugs, because we do not know that hemiplegia will pass off without the use of any. But confidence is not always a sign of sagacity, but may result because we have not made numerous *post-mortem* examinations. In the case instanced, there is a plug in the vessel, and consequent local softening. For drugs to do anything toward ridding the patient of his hemiplegia, they must help to get out the plug and to restore starved nerve tissue. Now, as a matter of fact, there is in these cases actual destruction of nerve tissue. If we could look into the man's head we should see that a part of his brain is boycotted. We cannot get at it by drugs.

There is another kind of so called syphilitic hemiplegia, essentially unlike the one already mentioned. The facts are, that a man, the subject of syphilis, has pain in the head for weeks—the best time for anti-syphilitic treatment—significant of the formation of a cortical gumma. One day he has a convulsion, very often beginning unilaterally, and after it he is temporarily hemiplegic (sometimes monoplegic). The process by which the hemiplegia results from syphilis is a doubly indirect one. No one supposes that the gumma discharges; but that the nerve-cells around about it do. Thus, the stages are—(1) Formation of a gumma; next (2) induction of instability by nerve-cells, exactly as by a glioma, possibly by a sort of encephalitis; then (3) sudden excessive discharge; and (4) consequent hemiplegia.

Syphilitic paralysis of a cranial nerve, and the two kinds of syphilitic hemiplegia, are utterly different in the pathological changes on which the symptoms directly depend, although syphilis is respectively the direct, the indirect, and the doubly indirect cause of them.

There is a class of cases of nervous disease—the neuroses—of which the pathology is unknown; chorea, epilepsy, insanity, neuralgia. In these diseases, little or nothing definite has, according to most authorities, been found *post mortem;* and, curiously, the fact that nothing is found, used to be considered proof that there was nothing to find. The statement that we do not know what there is in a particular disease, is sometimes taken to be equivalent to saying that there is nothing. We call the neuroses functional affections—a term, I submit, which should be kept for physiology. There can be no alteration of function without some material change. A man who does not make *post mortem* examinations may look on slight and transitory local paralysis as not depending on a material change, but if he did make such examinations, he would not hold that hypothesis. I repeat that we do not know the pathology of the neuroses. But now comes the curious point. We speak most confidently of the inheritance, interchangeability, and fundamental community of pathological character of those very diseases of which the ascertained morbid anatomy is nothing, or next to nothing. Thus there is assumed to be a community of nature betwixt epilepsy and insanity. It may be so. For my part I have not heard of any facts tending to prove anything of the kind. The evidence adduced goes only to prove that many epileptics become insane. The neuroses are spoken of confidently as being nervous diseases in the sense that the pathological changes begin in nervous tissues. Where is the proof, when we know nothing of their pathology? There is *no* proof. Again, pathology prevents our ideas on this subject being out of focus. Suppose a man has epilepsy, or paralysis, or chorea, and suppose that all his relatives had the nervous symptom or disease, hemiplegia; is there any proof that he inherits a tendency to a nervous affection—that his epilepsy is owing to his nervous tissues *beginning* to go wrong! Not the smallest; because the hemiplegia is owing to arterial changes. If the family history in such a case tends to prove anything, it tends to show that the pathology of the patient's epilepsy is primarily arterial, and only secondarily nervous.

There is a metaphysical pathology. The cases are those on which we either do not obtain *post-mortem* examination, or find nothing *post-mortem*. It is rather difficult to define metaphysics. Some people call psychology metaphysics; some call anything very difficult and complex about mind and body metaphysics; some use it merely as a term of abuse. It is, I think, a great pity that some metaphysics is not taught to students before they enter the profession. This may seem a strange remark, but the reason for making it is, not to urge that they should be metaphysical, but for the diametrically opposite reason that they should be less metaphysical. It is a mistake to suppose that those who write books on metaphysics are the most metaphysical. They have, at any rate, the knowledge that they are dealing with metaphysics. . . .

A good deal under the guise of practicality is pure metaphysics. There was once a man who could conceive an abstract Lord Mayor. The conception he had, so he averred, had neither head, arms, legs, nor corpulence; it was not an image of any particular Lord Mayor, nor a fusion of several, but an abstract Lord Mayor. Well, we think this metaphysician was too confident in his powers of conception. But do we not imagine ourselves capable of the same kind of marvelous feats? Let us look at a case of aphasia. A man does not speak, and yet can understand what we say to him, and can think—on ordinary things, at any rate. These are the facts; no one disputes them. Now comes the metaphysician, who proffers the explanation that the patient has lost words, but retains the memory or ideas of words. There are, it seems, words, and also memories or ideas of words, which latter, somehow, are not words. Now, what is an idea of a word which is not a word? It is, like the abstract Lord Mayor, simply nothing at all?

We should deal with the difficult and the complex in as realistic a manner as we do with the simple. The hysterical patient, who is said to have paralysis of the will, has some material change. What it is we do not know; and we never shall know, if we be content with metaphysical explanations, which, in one sense, explain everything, but really explain nothing. I have long expressed the opinion that, for the scientific study of diseases, we should regard them as examples of dissolution—using this term as the opposite of evolution. In this way we shall avoid the errors of confusing the psychical with the physical, and shall steer clear of metaphysical explanations.

Besides the sectional addresses already referred to, much interesting work was done in all the Sections. In most of them, in addition to the usual papers, special subjects had been selected for formal discussion. Thus, in the Medicine Section, the treatment of aggravated hysteria and allied forms of neurasthenic disease, chlorotic murmurs, and dropsy; in the Surgical Section, the early treatment of joint disease, and bone-setting; in the Obstetric Section, subinvolution of the uterus; in the Section of Public Health, the alcohol question, and the notification of infectious diseases; in the Ophthalmological Section, the extraction of cataract; a goodly array of important subjects. As it was impossible to be everywhere at the same time, I cannot say anything on these points, which I regret. In the Pathological Section, also, some interesting discussions took place,—first, on diabetes, in which Dr. S. Mackenzie, Dr. Pavy, Dr. Saundby, and others took part. Mr. Hutchinson opened a discussion on the origin of tumors, in which Sir James Paget, Mr. Butlin, and Dr. Thin took part. On the third day the subject of bacilli was gone into. Dr. Heron (London) demonstrated Ehrlich's method of showing tubercular bacilli; and Dr. Heneage Gibbes (London) demonstrated his own method. For this he claimed greater simplicity in all the details; the bacilli were visible with ordinary illumination and low powers. In the Surgical Section some interesting discussions took place. That on the treatment of joint diseases left us much where we were before. That on bone-setting, introduced by Mr. Marsh, followed by Mr. Adams, elicited a very good paper from Mr. Dacre Fox, who has had large experi-

ence, and is in a position to speak with authority on this matter. He especially advised greater attention on the part of medical men to the slighter forms of injury, and to sprains, from both of which injuries the older bone-setters had made nearly all their reputation. In the same Section, Mr. Lawson Tait read a paper on "A Series of One Hundred Consecutive Cases of Ovariotomy performed without any Listerian Details." He had had three deaths—one from accidental suffocation during vomiting, the other two from thrombosis, extending from the ligature to the heart. Of these 100 cases, 6 were pregnant; all got well; 1 aborted, the other 5 went to the full period. One had acute peritonitis at the time of operation; 3 got peritonitis during treatment. Of the 100 cases, 2 were solid fibromata of the ovary, both recovering; of the remaining 98 cystoma 11 were parovarian tumors; in 60, one ovary was alone affected—3 deaths; in 27, both ovaries were affected; all of which recovered. In 53 of the total number there were serious adhesions; in the three fatal cases there were no adhesions in two; slight adhesion in one. He attributed his success to the following points: First, to the abandonment of the clamp; secondly, to careful cleansing of the peritoneum; thirdly, to careful drainage; fourthly, to increased personal experience; fifthly, to the discontinuance of previous tappings (the two fatal cases of thrombosis had been tapped sixteen and thirty times respectively); sixthly, to the complete abandonment of antiseptics; seventhly, to the establishment of hospital discipline and hygiene.

American Dermatological Association.

The American Dermatological Association met in annual session at Newport, R. I., August 30, 31 and September 1. The President, Dr. J. Nevins Hyde, of Chicago, in addition to the annual address, read a paper on "Papillary Dermatitis of the Hairy Scalp," a rare form of skin disease situated at the junction of the back of the neck and the scalp. It consists of elevated patches, which, upon puncture, give exit to pus, followed by a sanguineous gummy fluid. The disease is due to an inflammation of the skin follicles.

Dr. C. Heitzman, of New York, read papers on "Myxo-angioma of the Skin" and "Ergot in Some Forms of Skin Disease." He recommends ergot, in half drachm doses of the fluid extract, several times daily, in pruritus and acne.

Dr. R. W. Taylor, New York, read "Notes on Psoriasis," in which he stated a syphilitic origin for one-fourth of his cases. Dr. George A. Rohi, of Baltimore, has observed two cases following vaccination with bovine virus.

Dr. Henry G. Piffard, of New York, read a paper on "Calx Sulphurates." He believes that acne can be successfully treated by sulphide of calcium, in doses of from one-eighth to one-sixth of a grain. Failures occur from giving it in too large doses. The composition of the drug, also, is very variable. He noticed that in a diabetic patient the sugar entirely disappeared while taking this remedy. Dr. William A. Hardaway, of St. Louis, illustrated, by a life-size painting, a curious case of pigmented neoplasm of the skin, which first appeared after the patient had unadvisedly taken large doses of iodide of potassium.

Dr. A. R. Robinson illustrated, by microscopic slides, a paper on "The Nerves of the Skin." He demonstrated that the nerves do not terminate in free ends, as usually supposed, but form loops, and return into the superficial or deep plexus, or into a neighboring papilla.

Dr. James C. White insisted strongly that leprosy is inoculable.

Syphiloderma papulosum carcinatum was talked about by Dr. I. E. Atkinson, of Baltimore. This rare cutaneous lesion belongs to the early stages of syphilis. The spots are due to a single papular development, which slowly enlarges until it covers a space as large as a silver dollar. The eruption may be sparse, or it may involve the entire body. Its course is slow. It resembles ringworm, from which it can be differentiated by the microscope.

Dr. White, Chairman of the Committee on Statistics, presented a tabulated report based on 58,617 cases of skin disease observed by members of the Association.

The next place and time of meeting will be Lake George, on the Wednesday nearest September 1st, and the two following days.

The following officers were elected for the ensuing year: Dr. R. W. Taylor, of New York, President; Drs. I. E. Atkinson, of Baltimore, and A. R. Robinson, of New York, Vice-Presidents; Dr. A. Van Harlingen, of Philadelphia, Secretary; Dr. George H. Rohé, of Baltimore, Treasurer.

Pharmaceutical Articles.

PACKER'S TAR SOAP.

Dermatologists are well aware that soaps made from rancid fats or by careless methods act as irritants to the skin, and both set up and maintain diseased conditions of its surface. A pure soap, carefully prepared from vegetable oils, is something worth knowing and having. We can speak from personal experience that Packer's Tar Soap meets these requirements. It is exceedingly smooth and agreeable to the skin, and as it is combined with pine tar, it is valuable as a remedy in cutaneous affections, as well as pleasant for a toilette article. We commend it, without hesitation, as the most satisfactory soap, in both these respects, that we have ever used.

The Duration of Isolation in Infectious Diseases.

The *Medical Times and Gazette* says that the Minister of Public Instruction some time since addressed a note to the Académie de Médecine, requesting that body to furnish him with an answer to a question of great importance to schools and families, viz., How long should a scholar suffering from infectious disease be kept separated from his schoolfellows? This was referred to a committee, consisting of MM. Roger, Bergeron, and Hillairet, and their report appears in the *Bulletin de l'Académie*, for July 18th. M. Hillairet, after stating the periods of duration of contagious action of the various diseases concerned, arrives at these conclusions: 1. Pupils attacked by varicella, variola, scarlatina, mea-

sles, mumps, or diphtheria, should be rigorously isolated from their schoolfellows. 2. The duration of this isolation should be forty days for variola, measles, scarlatina, and diphtheria, and twenty-five days for varicella and mumps. 3. This isolation should not be broken through before the convalescent has taken baths. 4. The clothes which the pupil was wearing when he fell ill should be passed through a stove at more than 90° Cent. of temperature, then submitted to sulphur fumes, and thoroughly cleansed. 5. Bedding and curtains of the room, the walls and furniture of the apartment, should also be thoroughly disinfected and washed, and then aired. 6. A pupil who has been attacked by one of these diseases while away from the establishment should not be readmitted unless furnished with a medical certificate that the above mentioned prescriptions have been complied with.

Galvano-cautery in Surgery.

We learn, from some remarks recently made at a meeting of the Medical and Chirurgical Society of London, by Dr. Felix Semon, that the credit of the introduction of the Galvano-cautery in Surgery, usually ascribed to Middeldorpf, of Breslau, is, in reality, due to Mr. John Marshall, of University College, the President of the Society. Mr. Berkeley Hill, we believe, deserves the credit for this vindication of his countryman's and colleague's merit.

Personal.

—Dr. David W. Cheever, of Boston, who has been nominated for the Professorship of Surgery in the Harvard Medical School, rendered vacant by the resignation of Dr. Henry J. Bigelow, is a son of the late Dr. Charles A. Cheever, of Portsmouth, N. H., and was graduated at Harvard College in 1852, and at the Harvard Medical School in 1858. He has since won a very eminent position in his profession.

Items.

—An important literary and scientific discovery is announced from Salonica. The works of the celebrated physician, Galen, which were supposed to have been lost, have been discovered by M. Papageorges. They are in manuscript; date from the fifteenth century, and appear to have originally formed 248 sheets; 144 are in good condition, 24 are mutilated or worm-eaten, and 80 are missing.

—Paris has a commission for regulating the height of buildings, which are graded to correspond to the width of the street upon which they front. Houses may be forty feet high on streets twenty-five feet wide. In no case are they permitted to be over sixty-five feet high, and only then when the streets are sixty-five feet wide or wider.

—A terrible death happened recently at Walsall, where a youth died in fearful agonies, from the effects of having drunk a mixture of nitric acid and mercury, in mistake for ginger beer.

—Lisbon diet drink is made as follows: Sarsaparilla 90, red sandal wood 90, white sandalwood 90, rosewood 30, guaiacum 30, sassafras 30, mezereon root bark 15, black sulphuret of antimony 60, boiling water 3600 parts; infuse for a night, boil down to one-half, and toward the end of the operation add liquorice 15 parts.

—In the loss sustained by Mr. James Mackie, surgeon to H. M. Consulate at Alexandria, by the destruction of his house in that city, is included an almost unique collection of calculi, the result of twenty-two years' surgical work in the Deaconesses' Hospital; also his library and all his surgical apparatus.

—Among the prizes awarded by the French Academy of Medicine at its last annual meeting, one of 10,000 francs, which is only awarded every six years, was divided between Dr. H. J. Bigelow, of Boston, and M. Th. Auger, Dr. Bigelow receiving 6000 francs and M. Auger 4000 francs.

—The seat left vacant in the section of Medical Physics and Chemistry of the Académie de Médecine, by the death of M. Briquet, has been filled by the election of M. Gariel, who received fifty-seven of the votes of the sixty-eight Academicians present.

—Admiring the example set by the Princess of Wales and many distinguished English ladies, the Parisian ladies are now sending flowers to the hospitals and to the sick poor.

—A remarkably low death rate is recorded at Dover, England, during the past quarter, the total deaths representing an annual rate of 9.1 per 1000 of population.

—M. Fauvel relates an instance in which he found a bullet in the larynx ten years after it had entered the head.

OBITUARY NOTICE.

DR. ANDREWS E. BUDD.

Dr. Andrews E. Budd died in Mt. Holly, N. J., August 12th, 1882. Dr. Budd was born in Woodbury, N. J., July 18th, 1816; attended a full course of lectures on medicine in the University of Pennsylvania, and graduated in the spring of 1842. He began the practice at once in Vincenttown, N. J.; removed to Medford, N. J., in 1845, where he practiced eighteen years. He removed to Mt. Holly, N. J., in 1863, where he practiced the remainder of his life. He was a member of the Burlington County Bible Society, and had held the offices of President, Secretary and Treasurer. He was a delegate to the American Medical Association at New York and Philadelphia, and was last appointed to attend the Association at St. Paul. For some time he had been an efficient ruling elder in the Presbyterian Church. Dr. Budd was eminently useful and influential in the church and community, and his removal is felt most deeply by all.

DEATHS.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

HERPES ZOSTER NOT A SKIN DISEASE.

BY C. C. THAYER, M.D.,
Of Clifton Springs Sanitarium, N. Y.

There are few diseases whose nosology has undergone such mutations as the one now under consideration. At one time it was pronounced an exanthema, Hippocrates; again, a corrosivous, Paulus Ægineta; again, a dartros, Alibert; again, a dangerous and malignant malady, Planter and Hoffman; again, a neuralgic affection, Rayer; again, a neuritis, Ziemssen.

Its pathological changes and morbid anatomy declared to be in the skin, Galen; in the mental emotions, see Gibert; in spinal ganglia, Bärensprung, etc. Its etiology, atmospheric changes, contagion, constitutional dyscrasia, etc.

Its treatment has been correspondingly varied. General blood-letting, vaccination, fomentations, plasters, ointments, lotions and actual cautery (the latter I saw lately recommended in the London *Lancet*).

Its changes in nomenclature are equally interesting and peculiar. Hippocrates called it herpes; Paulus Ægineta, a corrosivous; Pliny, zoster; Celces, ignis sacer; Cullen, erysipelas phlyctenodes; Sauvages, erysipelas zona; Willan, herpes zoster; Schwarz, zona serpiginosa; Alibert, herpes phlyctenodes, zona farmis, dermatoses eczematenses, cingulam, shingles, etc.

All the Greek and Arabian Fathers classified and treated it as purely a skin disease, except Ser. Mercurialis, who, strangely enough, never even mentions the disease in his able book on cutaneous diseases of the 16th century. Up to the beginning of the present century, nearly every author adopted the classification of the Fathers. Later, some have deviated in particulars; *e. g.* Alibert attempted to individualize several forms of herpes, and gave this the name dartu phlyctenöide en zone, which, though a step in advance, was, after all, virtually adopting the generic title used by some of his predecessors, which includes also erysipelas and pemphigus.

Later, Willan and Bateman presented a new and improved classification. And the same is true of Wilson, Fox, Duhring and others, who, looking back of the advanced manifestation of the disease upon the skin, recognize morbid changes peculiar to the disease elsewhere than in the skin, and primarily so.

Yet in many of our most prominent works on dermatology, herpes zoster retains its early classification among skin diseases. Within the last half century extended investigations have disclosed a remarkable discrepancy between the nature and seat of the primary morbid changes, and the classification of this disease.

1st. That morbid changes exist in the skin is sufficiently obvious.

2d. That they exist elsewhere than in the skin is also evident, by various incontrovertible testimony.

Rayer says zona seldom shows itself as a perfectly simple or uncomplicated disease. The lymphatic glands are often inflamed; pleurisy, bronchitis, diseases of the stomach and bowels are among the most common affections connected with—and that coincide with—zona. "I may

add that other morbid conditions almost always accompany this vesicular inflammatory affection of the skin."

If we turn to post-mortem examinations, the above proposition will be found to be fully sustained.

In *Centralblatt*, Wyss gives a very interesting and instructive account of a post-mortem case.

The post-mortem examination was conducted with great care. The herpetic vesicles and scabs were very accurately limited to the right side and to the parts supplied by the first branch of the right trigeminal nerve. The left eye was perfectly normal. The nerve above mentioned was found to be broader and thicker than that of the left side, of a deeper gray-red color, of softer consistence, and with several nerve fasciculi separated by grayish-red, soft tissue, containing many vessels. This alteration in its character extended from the point where it entered the orbit to the finest branches, as far as they could be traced with the simple lens.

The other nerves traversing the orbit were perfectly healthy. Outside the orbit, and extending from it to the ganglion Gasseri, the first branch of the fifth was surrounded by extravasated blood. On the proximal side of the ganglion Gasseri the fifth nerve was normal in appearance. The ganglion itself was larger, and somewhat more succulent than the left; upon its inner side was a red mass that appeared to be caused by ecchymosis.

The proper substance of the ganglion was not of a yellowish-white color, but bright-red.

The fifth nerve was healthy at its apparent origin from the brain, where it entered into the Gasserian ganglion. There were numerous ecchymoses.

Similar observations have been reported by Trousseau, Danielssen, Hutchinson, Hebra, Weidman and others. Fox records a case of Paget in which herpes affected the parts supplied by the infra-orbital, the anterior dental, and the anterior palatine branches of the superior maxillary nerve. After catching cold the patient was attacked on the third day with herpes of the cheek, side of nose, the upper lip, the palate and buccal membrane. The final results were in some respects remarkable, and in keeping with the explanation as to the implication of the main nerve trunk.

A bicuspid fell out on the sixth day, a second on the seventh, and later still the canine and two incisors while the alveolus in part necrosed.

3d. That morbid changes exist elsewhere as well as in the skin, and that *primarily so*, is equally evident. Pain is a characteristic symptom of this disease and is always from one to five days prior to the eruption, and is always in line with the nerve upon which the eruption subsequently appears.

Some of the most inveterate cases of occipito-facial neuralgia, toothache, and pleurodynia are precursors of herpetic eruption, and invariably indicate its relative location.

The popular notion that if the shingles completely encircle the body death would certainly follow (attributed to Pliny) is anatomically impossible, save in a double attack.

The above well authenticated post mortem reveals the primary morbid changes of herpes zoster to be in the neurilemma, nerve tissues, or spinal ganglia. Twenty years ago Bärensprung projected the idea that the primary seat of pathological changes was in the spinal ganglia. This was in opposition to the vaso-motor theory, arguing that vaso-motor disorders would not produce new products, as is the cases in herpes zoster. This idea of Bärensprung has been substantially endorsed by Esmarch, Charcot, McCrea, and others.

Lately two cases similar to each other have come under our care, illustrating this view.

I will mention one. Mrs. S., aged 65, was taken, December 5th, with a pain behind the right ear. Soon febrile symptoms appeared, and on the third day the pulse was 120, temperature, 100°. The pain, which had now become violent, resisting all treatment, extended from the base of the brain to the eye, on the right side. The fourth day the eye was injected and very painful, the right nostril swollen and closed.

A few distinct characteristic red spots now appeared on a clean base at the exit of the right supra orbital nerve.

These continued to increase in size and numbers, extending upon the forehead, and situated upon a narrow, swollen ridge, which ran, in direct line with the extension of said nerve, to the crown of the head, which was exceedingly painful to touch, much more so than other parts of the head. Herpetic eruptions also appeared on the right side of the nose. Upon the appearance of the eruption the pain began to diminish; still the patient was confined to her bed. The eruption lasted about ten days, when the scabs dropped off, leaving the parts very red and sensitive.

The diminished pain merged into a sore feeling, followed by an itching sensation, which often provoked the remark, "Oh, I wish I could scratch the inside of my head." A month has passed, and though the patient is pursuing her

usual avocation, the eye is still very red, and the other affected parts are in a state of hyperæsthesia.

If the above citations and considerations be correct, then herpes zoster is unscientifically classed among skin diseases.

Secondly, it is not of vasc-motor influence, but partakes of the nature of a neuritis, and, thirdly, the attending eruption is not the disease, but only an outward manifestation of it—a phenome non similar to that illustrated in meningitis and typhoid fever.

THE SALICYLATES IN ACUTE RHEUMATISM.

BY GEO. P. YOST, M.D.,
Of Loganville, Pa.,
Lecturer on Dermatology, Baltimore Medical College.

In order to treat any disease intelligently, we must look closely into, and have an intimate knowledge of, the etiology, pathology and morbid antomy of the disease under consideration; as well as know the physical and chemical action of the remedies which we employ in our endeavor to cure it.

So with the salicylates in acute articular rheumatism. To feel satisfied that we are justified in abandoning time-honored remedies for something comparatively new, we must inquire into the nature, source and action of the drug, and see whether it will counteract the morbid conditions in the body which bring on rheumatism. Having found this satisfactorily, and clinical evidence upholding the theory, we should not hesitate to give our patients the benefit of such proof.

The question, then, arises, Have we any one drug which seems to be theoretically indicated in the treatment of acute articular rheumatism, the clinical experience of which seems to uphold the theory? I must say that I believe that salicylic acid and its compounds hold that place in the treatment of rheumatism, and the object of this paper is to prove the correctness of my belief.

In order to do this, let us first look at the etiology, pathology, etc , of rheumatism.

The different theories advanced in regard to the cause of rheumatism may conveniently be classed under two heads; viz.: the increased fibrin theory and the lactic acid theory of Prout.

The first is, perhaps, the older of the theories advanced, and we can scarcely help but believe that the older observers found fibrin in the blood (an excessive amount, as they thought). Of course, if they found fibrin, it was abnormal, for normally fibrin does not exist in it—only its elements—which need an intervening (acid?) ferment to cause them to unite and form fibrin. (Faster.)

The acid theory is accepted by perhaps the larger number of observers as the true one; though denied by some.

This theory seems almost conclusive to the ordinary observer, from the fact that in nearly all cases of acute articular rheumatism we have acid urine and perspiration.

It is, at least, the theory upon which most practitioners based their treatment before the introduction of salicylic acid and its compounds.

I believe the "acid" theory to be the correct one; and the alkaline treatment to have been the proper thing as far as it went, but I believe we should go a step further; look for and treat the cause which produces this *acid* condition, which, it seems to me, has heretofore not been done.

Accepting either theory, treatment should be applied, not only to the removal of the existing condition or disorder, but remove the cause, stop the formation of acid in excess, or prevent the formation of the ferment which causes the unity of the fibrin elements (paraglobulin and fibrinogen).

Having now, as it were, the work before us, the question arises, have we any remedy or set of remedies that will meet the indications?

I cannot do otherwise but say, yes. In salicylic acid and its compounds we have the very remedies to do all this.

To prove the assertion, I will quote the results of a few experimenters and observers on the uses of said remedies.

In 1875 Dr. Ludwig Lelzeritz, in a series of experiments (with salicylic acid), found that in varying strengths it had the power to arrest the movements of bacteria and micrococci, as seen under the microscope.

About the same time, C. Neubauer, Kolb's illustrious student, in a number of experiments with the "salicylates," found them to possess preservative properties and prevent *acid fermentation.*

Accepting, then, Neubauer's results as true, we have only to show that the very morbid actions which these drugs prevent, are the ones which give rise to the phenomena of rheumatism, and we substantiate our affirmation in favor of the salicylates.

In support of this we find different observers

agreed upon the ferment theory giving rise to acid in excess.

Dr. Johnson, of Birmingham, in a paper read before the British Medical Association in 1875, says, as to the cause of rheumatism:

"The non-conversion of starchy food into glucose, in consequence of irritation from improper food, or from exposure to cold and damp, and the conversion, in the cæcum, of the undigested *starch* into lactic acid, which, being absorbed, produces the phenomena of rheumatism.

At a meeting of the Cambridge Medical Society, in 1880, Prof. Latham advanced still another theory as to how lactic acid is formed, causing rheumatism, and how the salicylates are beneficial. He says: "The first step was a lowering of the 'inhibitory chemical centres,' or nervous centres which control oxydation in the muscular tissue. Following up this, the oxygen in the oxyhæmoglobin, instead of entering the muscular tissue, to be exhaled therefrom in the form of carbonic acid gas, has its sojourn in the tissues shortened, and passed into the blood in the form of lactic acid. This acid, then, being rapidly oxydized in the blood, instead of the muscular tissues, develops an abnormal amount of pyrexia." Speaking of salicylic acid he says, "It lowers the temperature and cures the disease by chemically combining with the substances from which the lactic acid is derived, and producing less heat than would result from the oxydation of that substance."

Take the verdict of clinical observations, and what have we? Simply this: Looking over files of any live medical journal, for the last three or four years, we find them full of testimonials in favor of the salicylates. I will refer to a few; to quote them all would fill a volume.

Dr. Maclagan (*British Medical Journal*, 1876), says: "I have used salicylic acid in every case of acute rheumatism which has come under my care for the last eighteen months, with invariably the same result, a rapid cure of the disease." He further says: "Seeing a patient suffering from acute rheumatism, I have no hesitation in assuring him that within forty eight hours, possibly within twenty-four hours, he will be free from pain, etc."

In the report of the Leeds Infirmary, recorded in the London *Lancet*, we read of similar good results with the salicylates.

Dr. DaCosta and a host of others in our own country speak in a similarly favorable manner of it.

So far as my observations go, I must confirm the favorable reports of others, for I have had good effects from it for the last four years, in all cases but one (in which it did no good). In two cases it acted so strikingly favorably, that I would not feel as having done my duty toward my rheumatic patient, did I not give him the benefit of the salicylates.

I use the salicylate of soda. In one case it relieved all pain and fever in twenty-four hours, and in another one in eighteen hours.

I do not wish to prolong this paper by the rehearsal of cases with full notes, or any new ideas, for I claim nothing new; but if the collaboration of these few facts, gathered here and there, will induce some over conservative medical brother to give his suffering patient the benefit of a trial of the salicylates in rheumatism, I will feel paid for my little labor.

So thoroughly am I convinced of their efficacy that I believe they (salicylates) will become to rheumatism what quinia is to malaria.

A NEW ANATOMICAL TRUSS IN THE TREATMENT OF RUPTURE.

BY J. H. WARREN, A.M., M.D.,
Of Boston, Mass.

The subcutaneous method of injecting the hernial rings is no longer an experimental operation or one of doubtful expediency. It is an established and successful procedure. Of course, it has not in the hands of every surgeon been every time successful. It has had its failures, and who is able to mention the simplest surgical operation of which the same cannot be said. When, however, I consider how sadly its elements and principles have been misunderstood by many of the profession, who are looked upon, moreover, as authorities in surgery, I am more than astonished that it has met with such almost universal success as it has. Some even now think that the success of the operation depends upon setting up an inflammation in and around the sac; that is, a peritonitis; others as unreasonably suppose that we avoid all inflammation whatever and excite only an imaginary "tendinous irritation," so called. Few comprehend that the operation, while it avoids general peritonitis, strives to excite an inflammation in the fibrous tissues of the rings and the canal, and that there is no such thing as a tendinous irritation, in the sense in which it is commonly used.

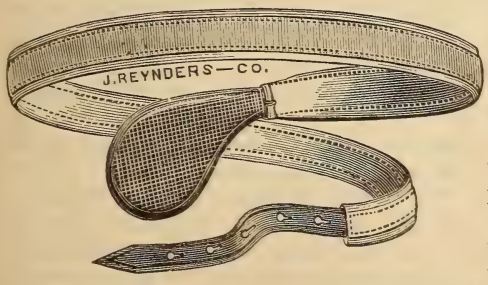
When the operation has been properly performed, and with an understanding of its surgical requirements, it has, so far as I can ascertain from trustworthy data, been successful to such an extent that I do not think I am egotistical

or over sanguine when I say that, in my knowledge and experience, there is no operation for hernia which promises so much for the patient and disturbs him so little. All success with the operation, however, is dependent upon the care with which the minutest details are scrupulously observed; and I maintain that when the proper instruments and sufficiently stimulating food is employed in the proper manner, one important step in the operation has been well taken. These principles and details I have endeavored candidly to present to the profession in my "Practical Treatise on Hernia."

Another important element of success remains to be considered. When I began to operate for hernia by the method of subcutaneous injection, I was troubled to obtain a suitable truss to be worn by the patient, and one that I could conscientiously recommend. The trusses that are in common use are constructed upon a plan that is entirely erroneous and absolutely injurious. They have a pad of wood or metal, stuffed with hair or some soft substance and covered with leather. They are thus very heating and inconvenient to the patient, because they prevent the exhalation of moisture and perspiration from the body.

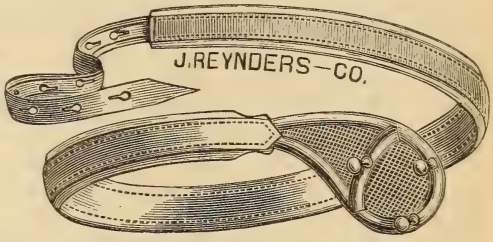
This is not, however, their only defect, nor is it their most serious one. The shape of the pad is convex and in direct antagonism to the anatomy of the parts to which the truss is applied. By its constant pressure it has a marked tendency to dilate, weaken and paralyze the rings, instead of contracting and strengthening them. Thus, in the course of time, the pad that has been worn is no longer sufficient to retain the hernia, becomes painful and even unendurable, and finally has to be thrown aside and a larger pad applied.

Recognizing these deficiencies, I have devised a truss which I think will meet all the demands. The pad is composed of a rim of tubing, in sizes from Number 12 to 21, over which a very fine



wire gauze is tightly drawn and neatly soldered. The plane of the pad is slightly concave, in order to accommodate it to all the anatomical relations, and can be still further adjusted by the surgeon to any individual case. The gauze being drawn tightly over this rim gives us a flat pad, which presses upon the body like the human hand, the best of all trusses. The pad is soldered at its neck to the spring, and is so shaped that it will not press upon the spermatic cord, in scrotal hernia, nor too hard upon Poupart's ligament, in femoral. Neither will it glide over the ligament and slip into the groove of the groin, as does the common pad.

There is a bridge of tubing over the pad, which serves to strengthen it, and may also assist in retaining in apposition to the body a sponge, either medicated or moistened simply with cold water, for the purpose of reducing inflammations. The pressure of the pad can be applied in any



direction, as there are three knobs for the attachment of the strap.

Between the pad and the integuments a layer of cotton flannel, either single or double, should be placed; this can be renewed by the patient as often as desired. The perineal band consists of a small gum-rubber tubing, or a coarsely braided silken cord. This will be found far more comfortable to the patient than the flat and sharp-edged strap, which soon cuts and chafes.

It will be evident to all that this is a very light and comfortable truss. It is hygienic, and is accurately fitted to the parts. It is anatomical, because it tends to draw the pillars of the rings together rather than to separate them. Hence, even if used without the operation of injection, such a truss is better fitted to effect a cure of hernia than any convex pad in use.

The springs are of varying degrees of stiffness. One is very soft and gentle in its action, and is more especially adapted for use after the operation of subcutaneous injection. It can be applied eight or ten days after the operation. Others are stronger and are better adapted for those forms of hernia where a truss is to be worn without an operation having been performed. They can be worn with perfect ease, night and day, without removal, as they are non-corroding, and are covered with the best grained or Russia

leather, made impervious to water by the process of the Boston Waterproofing Company.

These trusses are so radically different from all preconceived ideas in the application of all artificial support, that it might, at first sight, seem to some, especially to those who are manufacturers of surgical instruments, that the springs are too gentle in their action. This is an error, for one would soon find it physically impossible to wear an ordinary truss with a stiff spring night and day. The spring is made gentle for a purpose, and this purpose would be defeated by a stiffer spring. Nor is it necessary, with this anatomical spring pad, to bind a man with a stout, stiff hoop. A very gentle pressure, if only properly applied, will be sufficient to give adequate support.

To show the value of this truss, it will be necessary to give only a few characteristic cases from my clinical experience, which has been by no means limited in this direction.

Mr. G., age 40, with a large, direct hernia, was operated upon subcutaneously, in the early part of the summer of 1881. Ten days after I injected him with my Formula C I applied the anatomical truss, which he continued to wear, night and day. The result was a perfect cure of the hernia, so that he was able to abandon the use of the truss from that time. While he was wearing the truss he met with two accidents—one a fall down a flight of stairs; the other a violent strain while righting up a coal cart. Notwithstanding all this, the result was a perfect cure of the hernia, so that he was able to abandon the use of a truss after having worn it three months.

Mr. C. McC. was operated on early in October, 1881, for a double oblique inguinal hernia of ten years' duration. Eight days after the operation I applied this truss, which he wore for three months, night and day. During this time he slipped on the ice and was slightly re-ruptured on the side where the larger hernia had been. He consulted me about the first of January. I found the new hernia to be a direct one. I ordered him to continue to wear the truss, and in April found him cured on both sides. He wears the truss now for safety, whenever he is to undertake any heavy work requiring violent exertion.

Dr. D. was operated upon in November, 1881. He was 54 years of age, and was ruptured on the left side when 20 months old, by a nurse falling upon him while carrying him in her arms. The hernia was very large, the scrotum being filled and distended with intestine and omentum. All kinds of artificial supports had been applied without the least benefit. Finally, the parts became so irritable that no support could be endured. The doctor is a liberally educated, conservative gentleman, and a surgeon of experience in the late Confederate Army. To give his evidence upon the value of the anatomical truss and operation, I quote from a letter written to me by him on May 22d, 1882. He says: "My general health has been excellent since I saw you, and I am persuaded that the operation for hernia will prove an entire success. By strict observance of all your instructions, I have escaped all accidents, and feel as strong and sound in the region of the operation as I do upon the opposite side. I cannot imagine a case that could have progressed more favorably or promised better results. I have frequently placed my fingers on the truss pad during the act of coughing and sneezing, to receive the impulse of the viscera, but cannot detect that there is any more sensible movement communicated by the pad than the general vibration felt over the entire abdominal wall.

"It is difficult for one like myself, who has been so long impeded in his movements, and who so suddenly regains or rather acquires strength and a feeling of security from danger, to restrain himself from excesses, and the effort to control my exuberant spirits is almost beyond my power of will."

This was one of the most hopeless cases I ever operated on, and had the patient not been a physician, who knew how to take care of himself, I should not have undertaken the treatment.

To illustrate the well known fact that recent hernia may often be cured by wearing a truss persistently, even without any operation, I select the two following cases:—

Mr. W., a builder, aged 35, referred to me by Dr. W., had a direct hernia upon the right side, of about the size of a hen's egg. I, being sick at the time, postponed the operation for six weeks, advising him in the meantime to wear a truss. At the end of this time I found the rings so firmly united and occluded, from the wearing of this truss night and day, that no operation seemed necessary. At the time of writing this the patient seemed cured, without operation.

Mr. B., aged 30, applied to me in December, 1881, with a small hernia, caused by a violent fit of coughing. Being engaged with more formidable operations at that time, I deferred operation upon him for a few weeks, advising him, meantime, to wear a truss night and day. He neglected to present himself for operation until

early in May, 1882, at which time I considered him entirely cured, and advised him to discontinue wearing a truss.

These two latter cases illustrate the well known fact that recent hernias can often be cured by persistently wearing a truss, even without any operation. If, then, hernia can be cured in its early stage by a properly adjusted pad, it is not surprising that old hernias can likewise be cured by a suitable pad, if once the fibrous rings are freshened and stimulated into activity.

Finally, if by any of my writings I have aroused any new zeal in the profession for the study of this operation, and caused the mist that was hanging over it to disappear in any degree by study and investigation, I shall have accomplished one great aim and desire that has urged me on.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. W. H. DRAPER.

Reported by H. H. Seelye, A.M., M.D.

Laryngeal Phthisis.

The patient's name is M. T.; is a native of Ireland; aged 35; single; a shoemaker by trade. He was admitted to the hospital on October 25th, 1881. Has been a moderate drinker. His family history is negative, but three of his family died in infancy. He had never been sick until last March. Two years ago he came from Australia, where he had been living. Seven months ago, while in Nebraska, he caught cold, which caused him to cough and expectorate a good deal. But he got better and was comparatively well until about three months ago, when he began to get worse. He complained of a pain in his chest, loss of strength, night sweats and shortness of breath on exertion, and he became so weak that he was obliged to give up his work. These symptoms steadily increased in severity until about a month or six weeks ago, when the night sweats ceased. But his skin and mouth now became dry, and there was a sense of irritation in the mouth and throat, which caused him to cough a good deal. In this condition he came to the hospital. He had no diarrhœa, and no gastric or urinary symptoms. On admission his pulse was 87, respirations 32, and temperature 100.9°.

Gentlemen, there are certain features in this history which I think are worth speaking about. The disease appears to have originated six or seven months ago, in a man who up to that time was in good health, and according to him it started from a cold. And he says that he first lost his voice a month or five weeks ago. The first point to notice is that though he began to cough in the spring, yet he got better and had no special trouble until three months ago, and there were no laryngeal symptoms until six or seven weeks ago. And since that time he has lost his voice, and coughing and speaking have become painful, but deglutition, which is often very painful in these cases, is not so here, as yet. This history, then, would seem to indicate that the disease began in the lungs, and it had made considerable progress before the laryngeal trouble began. This is the usual history of so called "laryngeal phthisis." I speak of this fact because many of these patients are treated as cases of local laryngeal affections, and often painful and irritating applications are made to the larynx, when the serious part of the disease is not here, but in the lungs.

Another point in these cases is that the lung disease is often, and I may say, generally, limited in extent, and the constitutional symptoms are out of all proportion to the extent of the local disease. So these patients take no notice of the phthisical trouble, but they come for relief of the laryngeal distress, and then, upon examination, it is found by the physician that the phthisis is the primary and important malady. We will now see what the physical examination will show in this case.

Inspection.—The patient is quite emaciated, so that the ribs are prominent beneath the skin. The superior and inferior clavicular regions are both depressed. The cardiac pulsation is quite marked, and it is diffused over a considerable space, and a little higher up than normal.

Palpation.—The expansion of the chest seems a little more marked on the right side. The vocal fremitus cannot well be obtained, because of his aphonic condition.

Percussion.—There is slight dullness in front, over the apex of the right lung. Over the same region, on the back, there is decided dullness; and also slight dullness in the supra-scapular fossa on the left side. The area of dullness on the right ceases in the infra-scapular fossa, and below this there is good pulmonary resonance.

Auscultation.—Over the upper portion of the right lung, posteriorly, the respiratory sounds have a bronchial rather than a vesicular character, and the expiratory sounds are so prolonged as to nearly equal in length the inspiratory, and they are blowing in character. True vesicular or slightly exaggerated breathing is heard below this region. Over the front of the chest, at the upper portion of the left lung, the inspiratory sounds are harsh, and whistling, and prolonged. On the right, some sibilant and moist ronchi are heard on inspiration, over the region of percussion dullness. The vocal sounds seem to come directly to the ear, through the chest walls, as if they were made immediately beneath the ear. This is the usual quality of the bronchial vocal sounds as distinguished from the laryngeal sounds in health.

You will find the vocal sounds a valuable sign in indicating the presence or absence of pulmonary consolidation, and it is an important point in an examination to be able to tell the degree of consistency of the lungs.

The appreciation of the vocal sounds is very easy to acquire, for in health you can easily distinguish that the voice is formed in the larynx, and it sounds as if it were at a distance, and as if some one else were speaking to you. But in

consolidation of the lungs, because consolidated lung tissue is a better conductor of sound, the voice seems to be made directly under the ear. This is not as good a patient as some, to illustrate this difference between the voice sound in healthy and consolidated lungs, because he has some pulmonary trouble on both sides.

In the majority of cases of phthisis, as you know, the disease first manifests itself at the apex of the left lung, while pneumonia attacks the right. But I think that in laryngeal phthisis the lesion in the majority of cases is in the apex of the right lung, and is usually very limited in extent. The disease in this man is not far advanced, and I doubt if there is yet any excavation in the right lung. The left lung is but slightly involved. He says that when he was traveling in Nebraska, he was accustomed to carry his heavy tools over his right shoulder, and this caused him pain at the time. So he thinks that this might have had some influence in causing his present trouble. I am not prepared to say at present how far this inference may be true.

There is ordinarily pretty high temperature in cases of this kind. But here, on one or two occasions recently, it has been normal in the morning, and ranging between 101°, 102° and 103° in the evening. The emaciation has been rapid, as it always is in continued fevers, and he sweats profusely every night.

Treatment.—The special indication for treatment in most of these cases, is to relieve the local distress. As I told you, these are cases which are often treated for a considerable length of time by specialists in laryngeal diseases, and stimulating or astringent local applications are made to the larynx. But the patient gets no better, and ultimately the discovery is made that the real disease is a pulmonary phthisis. And there is no possibility of curing the ulcers, which may be on the vocal chords, so long as the pulmonary disease exists. The disease itself causes the larynx to become hyper-sensitive and irritable, and I think that this difficulty is often aggravated by the ordinary local applications, so that their employment is unwise. But coughing, talking and deglutition often become very painful, from the irritation and inflammation of the muscles of the larynx, and the relief from suffering which this distress calls for is, I think, the most imperative indication for treatment. This end can best be accomplished by means of opium. It may be administered by the stomach or by hypodermic injection, but it is more successful if used topically, and applied directly to the ulcers in the larynx. This may be accomplished by the insufflation or blowing of morphia powder alone, or combined with bismuth or chalk, directly upon the sores. The operation is simple and easily performed. You may take from $\frac{1}{6}$ to $\frac{1}{4}$ grs. of morphia and mix it with a few grains of powdered chalk, and blow this into the throat by means of an ordinary insufflator, or through a paper tube of the proper size, which you can easily make yourself. This causes the powder to be deposited upon the tender ulcers in the larynx, and the relief is almost instantaneous, and it lasts for some hours. This simple plan of treatment should, therefore, not be neglected.

Phthisis.

Here is another patient, gentlemen, who says that he was taken ill two weeks ago. He admits, however, that he had a cough last winter, which persisted for some time, and he then lost his voice, which, he says, he always does when he has a cold. His throat was inflamed at the same time. He was treated for this trouble, and got better, but he still coughed a little during the spring and summer. He does not think he has lost flesh. A few weeks ago he says that he fell down stairs, and this was followed by a hemorrhage from the lungs. Since then his troubles have increased until he came to the hospital.

You see how difficult it sometimes is to get at the beginning of a phthisical disease. For these patients are usually hopeful, and they will not for a long time admit that they are ill. They will sometimes date the beginning of the disease from a recent cold or hemorrhage, but you yourself will often be obliged to date it from the time when they began to lose flesh. And this is a very good point for you to start from, for fever is one of the early phenomena of phthisis, and fever is always attended by emaciation.

Palpation.—There is no marked difference in the expansion of the chest on the two sides, but it seems to be a little freer on the right.

Percussion.—In front, over the apex of the left lung, there is dullness. On the right the pulmonary resonance is increased. The same conditions hold posteriorly, but to a less degree.

Auscultation.—There is prolonged expiration on both sides. The respiratory murmur and the voice-sounds are most distinct on the right, but the latter seem to be made at a distance from the ear.

He seems to have some trouble at the apices of both lungs, but the morbid process is more advanced on the left than on the right side.

Asking the patient to cough is a good means of getting at the effects of a full inspiration. Sometimes it is difficult to get patients to breathe so that you can get any satisfactory information, and this is especially the case with nervous, hysterical and delicate women, as well as men. But if you can get them to coughing, and so make them take several deep inspirations, you may get a good deal of information in this way, which you would fail to get upon the ordinary efforts of the patient.

This man is a good deal better than when he came in, so far as his voice is concerned. His voice is now fair, and this is so far an evidence of the good effect of treatment. But the usual history is that the laryngeal trouble advances *pari passu* with the pulmonary disease; and the treatment of the laryngeal difficulty, in these cases, is usually of no use, unless you treat the phthisis also.

Sanitary Museum of New South Wales.

The Colonial Government are making rapid progress with the organization of a Sanitary Museum of New South Wales, which has been permanently established at Sydney. Arrangements have been made for the shipment of contributions, in the shape of sanitary appliances, from England.

Editorial Department.

Periscope.

The Rapidity of Visual Perception.

The *Lancet* says that M. Charpentier has endeavored to determine (as others have previously done) the interval which elapses between the appearance of a light before the eye and the production of a signal by the subject as soon as the light is perceived. In the course of these experiments, he ascertained whether the interval is the same for the central and peripheral parts of the retina, whether exercise is capable of modifying the duration, and whether such modification produced by exercise is or is not limited to the part exercised. In these experiments, the eye, fixed in the centre of a perimeter, was directed towards the bottom of a large box lined with black, in which a hole was made, a square centimeter in size, opposite a well-lighted window, but usually closed by a black metal plate. This plate was kept in position by an electro-magnet, so that it fell immediately as soon as the circuit was broken, and the interruption was also indicated by an automatic registration on a revolving cylinder. This marked the moment at which the window was exposed. The pressure of a button, the moment the light was seen, re-established the circuit, which was also marked on the registering cylinder. The interval between the interruption and restoration of the circuit, measured by the vibrations of an electric chronograph, indicated the time necessary for the individual to perceive and to signal the light. This perception interval, "personal equation" (which M. Charpentier calls by the somewhat misleading term of "duration of luminous perception"), is found to vary for the same person and under the same conditions, the longest interval being about double the shortest. But the mean of a series—say ten—is found to be the same for the whole period of the experiment. In the case of the author, for instance, with daylight, the average period was found to be .13 sec. The interval varies also in different persons, from .09 sec. to .15 sec. Under normal circumstances the interval is the same for each eye. It is notably augmented by another cerebral occupation imposed on the person during the experiment. If the subject talks, for instance, or listens attentively to a lecture or a conversation, the latent interval may amount to .04 sec. or .06 sec. more than when all his attention is concentrated on the observation. The interval is always greater for indirect than for direct vision, and it is the longer the further the point stimulated is from the centre of the retina. At first the difference is very considerable, amounting to as much as .07 sec.; but it lessens gradually during a long course of experiments, and at the end of six weeks did not in one case exceed .02 sec. The difference cannot, however, be altogether removed by exercise, which also lessens the interval for direct vision. Having ascertained that the interval was the same in each eye, M. Charpentier made, every day during six weeks, fifty observations at two points, one at the centre and another 80° distant from the centre in the outer part of the visual field. At the end of this time he was in a position to appreciate the influence of exercise on these points in the other retina, and also on other points of the two retinæ. The interval attained was for the centre of the left eye .129 sec., and for the unexercised centre of the right eye .143 sec. At the peripheral spot in the left eye an interval of .1 sec. was required, and at the corresponding point in the other eye .210 sec. This exercise had notably lessened the interval at the points used in the left eye. It was interesting to ascertain whether it had had any influence on the points not exercised in this eye. It was found that the interval was similarly lessened for all peripheral points in the outer half of the field, but not for those in the inner half. Hence exercise of one eccentric point seems to influence all points of the same half of the retina, and not those of the other half. More, this influence had extended to the corresponding half of the field of vision of the opposite eye, in which the interval was much shorter than in the non-corresponding half. This can only be explained by admitting the semi-decussation of the optic nerve fibres at the chiasma, and supposing that the exercise influences, not the retina, but the centre which receives the impressions from the corresponding half of each retina. M. Charpentier seems to have attended, in his conclusions, too exclusively to the sensory part of the process which he has measured, since a considerable part of the interval must have been occupied by the motor process involved in giving the signal. It is, therefore, clearly incorrect to speak of the interval as simply the "duration of perception." This consideration, however, brings out a new point of great interest. *A priori*, it might have been expected that exercise would have lessened the interval for the parts of the retina not practiced, although in slighter degree, because the effect of exercise in abbreviating the interval must be supposed to tell upon the motor as well as the sensory portion of the process. But this seems not to be the case. The interval for the non-practiced halves of the retina was not shortened, and hence exercise seems to facilitate chiefly the sensory portion of the process.

The Disease of Inebriety.

Dr. T. D. Crothers thus writes, in the *Medical Annals*:—

Inebriety was recognized as a disease long before insanity was thought to be other than spiritual madness or a possession of the devil. Those who assert that inebriety is always a vice, and that the disease theory is only an "ism" of our times, are merely advertising their ignorance of both the past and present history of the subject. The term inebriety expresses the general disease, of which the excessive use of alcohol is always a symptom. Alcoholism is a term used to designate a special class of symptoms coming

directly from the toxic use of alcohol. Drunkenness may mean or designate any state that follows directly or indirectly from alcohol. It has no definite meaning, and should never be used in scientific parlance. Dipsomania and mithomania are special forms of inebriety, marked by an uncontrollable impulse for alcohol, of limited duration, and with distinct free intervals of sobriety.

Alcohol is not the only cause of inebriety, but in a large number of cases the use of this drug is only a symptom of central nerve degenerations. From conditions more or less unknown, the use of alcohol (or any of its compounds) has been found to relieve some state of exhaustion, and its use afterwards is demanded as positively as food is called for to supply the nutrient wants of the body. The state is similar to that of the neuralgic who finds perfect relief from some form of opium; and this revelation is never forgotten or ignored. In a large proportion of cases alcohol merely explodes diseased states, giving form and direction to what might have been insanity, paralysis, rheumatism, or any of the various forms of diseases of the heart and lungs. From inheritance come all the degrees of exhaustion, feeble powers of resistance and inability to recover from any strain or loss, associated with special tendencies to certain forms of degeneration. Traumatism is another field of cause almost unknown. Psychical traumatism, where the effects of powerful emotions and conditions of nerve trepidation and exhaustion from mental causes are followed by changes and diseased states as clearly traced as tangible lesion of the surface. Every inebriate is suffering from both a physical and psychical disease, beginning from definite causes, and following a regular progressive march, from stage to stage, to either recovery or death. Every inebriate who walks our streets is a more wonderful subject of both pathological and psychological study than any other disease known to science. The range of symptoms crosses and recrosses the mysterious border land of health and disease, sanity and insanity, and often baffles the profoundest intellect to trace its march. Yet in all cases the natural history and outline of progress can be made out, and the general principles of treatment ascertained and applied.

Inebriety is curable in its widest sense. Not by any specifics or class of medicines, appeals to the pride of character or the religious emotions of the patient, or the faith and will power, but by the exact application of physical means suited to the wants of each case, along the line of natural laws. The inebriate is a sick man, and must be studied and treated as such. The causes of inebriety and the many complex forces and influences whose effects are emphatically physical, must be studied for the indications of the form and treatment necessary. To accomplish this the patient must be often quarantined, as in case of yellow fever. All the surroundings and conditions of life must come under the direction of a physician. He must be in an asylum where all the sanitary causes can be effectually removed, of which alcohol may be often an insignificant one. Here the building up process and rest essential to give the natural energies opportunity to become restored can be most effectually carried out. All the means known to science can be gathered and applied in an asylum or home, under the care of a physician, better than elsewhere. Our peculiar civilization is becoming more and more charged with the germ causes of inebriety, and statistics show that it is increasing far in advance of the ratio of growth of the population. The time has come for a general scientific study of this subject by the medical profession, above the superstitious levels of reformers and clergymen's labors. The medical profession should teach what inebriety is, and how to cure and prevent it, and not clergymen and inebriates themselves. It would be equal propriety to trust to clergymen and the views of those who had recovered from typhoid fever for information about the nature and treatment of this disease. Yet there are many physicians who practically endorse the most absurd theories of the nature of inebriety, or stand aloof and sneer at all efforts of every kind to reach this evil. The agitation of churches and societies to find some remedy is an unmistakable evidence of the stage of superstition, of one of the great scientific advances of the century. This is the opportunity for medical and scientific men. A new land, whose mountains, lakes and rivers are all unknown, opens up its mysteries for the pioneer. Already many men all over the world are entering this field. In Germany, last year, over one hundred papers and lectures were published devoted to this study. In France and England over a hundred more were published, treating the subject from the side of science alone. In this country inebriety as a disease is more thoroughly known and understood than in any part of the world. Yet the literature is very imperfect, and, like the study, in its very infancy compared to what it will be in the future. The great central truths upon which all the studies, both past and future, will revolve, are, that inebriety is a disease, and is curable as other diseases are. From this standpoint the profession everywhere is called upon to make accurate clinical studies of cases, and bring out the great laws of inebriety which shall supplant the ignorant dogmatism of enthusiasts and reformers.

Infectiveness of Tubercle.

In the course of an address on this subject, by Dr. William Pirrie (*Lancet*) the following specially interesting points occur. It has been said that one-seventh of all the deaths throughout the world and one-third of the deaths in active middle life are caused by tubercular disease. If this be true it must be all important to be familiar with every addition to our knowledge of this disease. The contagiousness of consumption has not been promulgated for the first time in our day, for Galen believed in its contagiousness, and ordered consumptive patients to inhale the vapors from the crater of Etna, while Morgagni, in his day, was of the same opinion. We read also that this belief has always prevailed in Italy, Spain and other countries of Southern Europe. In 1865 Villimin commenced a series of experiments to show that tubercle was an infective disease, and demonstrated the fact that caseation

of the tuberculous matter was not necessary to make it a focus of infection. Chauveau, of Lyons, obtained like results from all his experiments, which were of three kinds. First, he gave some oxen, by the stomach, portions of tuberculous matter procured in some instances from man and in some from oxen, which are very prone, as a class, to what is known by the names of "pearl disease," "angle berries," or "grapes," from the peculiar condition of the serous membranes, or, generally, bovine tuberculosis; second, he inserted particles of tuberculous matter into the connective tissue; and, third, he injected into the veins water into which tuberculous matter had been placed and had been filtered. In all cases tubercle granulations were found in the lungs, and all the animals contracted tuberculosis.

We may here conveniently mention that Dr. Charles Creighton, in his interesting work on bovine tuberculosis in man, published last year, describes numerous cases in which a condition of organs in the human subject was found similar to that seen in oxen dead of tuberculosis; and he establishes the extreme probability that the disease is not unfrequently transmitted to human beings through eating the flesh or drinking the milk of diseased cows. Professor Gerlach also states that healthy oxen can be infected through the milk of sickly cows, or by taking with their food portions of tuberculous matter from the organs of affected animals. Again, in France, M. Giboux operated on rabbits directly with the air itself expired by consumptive patients, with a view to determine whether it could induce tuberculosis in healthy animals. Into one room he placed a cage containing two healthy rabbits, and into it he passed daily, for some time, twenty or twenty-five litres of air expired by phthisical patients. Into another separated room he placed a second cage also containing two healthy rabbits, and into it he passed daily a similar amount of air expired by consumptives, but previously filtered through tow charged with carbolic acid. The consequences were, that at the end of about three months the rabbits in the first-named cage became emaciated and showed signs of disease, and at death tubercles were found in all the organs, but especially in the lungs; whereas, in the second pair of rabbits there seemed to be no injury to health at the end of a like period, and their organs, when the animals were killed, were found free of tubercles.

We have thus traced a belief in the contagiousness of consumption, held by a few probably in all ages, springing from observation and practical experience; and we have seen how it is justified by the results of experimental research in our own days, and that at last, within the past few months, the precise infecting parasite has been made a subject of microscopic demonstration.

The question now arises, If consumption is an infective disease, can anything be done to destroy its virulence, or to arrest its ravages to a degree hitherto unattained? This much we may safely assert, that the results of all the experiments we have detailed clearly indicate the need of recognizing the parasitic origin of tubercle, of fortifying the body against the inroad, and against all circumstances favorable to the development of the bacilli, as well as of aiming at the destruction of those already pervading the infected organs. With this in view, we must remember the importance of attending carefully to the improvement of the general health of all consumptives; to the avoidance of close confinement in overheated and over-crowded rooms, to the keeping the patient as much as possible in the open air in suitable weather; to the careful ventilation of sleeping apartments and sitting-rooms, while guarding against preventable draughts; to the separation of the healthy from the sick as far as possible, at night; and to warning the healthy against all avoidable inhalation of the breath of consumptive patients, who, in their turn, must be kept from re-breathing their own breath. Serious attention should be bestowed also on the disinfection of the sputa of consumptive persons; and much good may be expected also from the more assiduous use of antiseptic inhalations than has been practiced in the past.

Perhaps in all that has been said we may find a plea for cottage hospitals in open, suburban parts, in place of general or large special hospitals, for consumptives; and one, without doubt, for a more careful supervision of the health of cows, whose milk is an article of daily use by the consumptive, and enters so largely into the dietary of all non-consumptives, especially into that of children; as we are told the milk of animals suffering from tubercular disease is capable of transmitting it to previously healthy human beings.

Resection of Carcinomatous Large Intestine.

The Edinburgh *Medical Journal* quotes as follows from Richter, in *Centralb. f. Chirurgie*:—

The patient, aged 33, had been frequently under treatment for stenosis of the intestine (said to be the result of dysentery) situated in the region of the sigmoid flexure, where a firm, cord-like swelling could be felt through the abdominal walls. At length the patient's symptoms became so urgent that immediate operation was resolved on. The abdomen was opened in the linea alba, the distended small intestines, wrapped in disinfected cloths, were drawn to one side, and the stricture, seated a little above the sigmoid flexure, was exposed. The affected intestine, drawn well forward, was divided by a transverse incision immediately above the point of stricture, and a large quantity of very offensive, tenacious, fluid fecal matter was evacuated: but in spite of this the distention of the small intestines was scarcely diminished. The gut was then punctured in several places with a trocar, the gas and feces expressed, and the punctures closed with catgut sutures. The portion of intestine which had been drawn forward was then disinfected and replaced *in situ* above the stricture. The lower end of the colon was kept closed during the operation, by the fingers of an assistant. Three inches of the strictured portion of the gut were then excised, and the upper tube was joined to the lower by means of Czerny's suture. The short mesentery was treated in a similar manner. The point of union was then fixed opposite the inferior extremity of the wound, in

the parietes, which was left unsutured in its inferior fourth. Finally, a Lister's dressing was applied. Duration of the operation, three hours. On examination the stricture was found to be cancerous. A small stool was passed only a few hours after the operation; but on the eighth day, fæces and flatus escaping through the wound, the Lister's dressing was abandoned and open treatment adopted. Gradually the stools began to pass *per vias naturales*, and by April 19th, or fifty-four days after the operation, the patient was able to spend the greater part of the day out of bed, although for a month more there was an evening rise of temperature. The fistula at last healed under applications of the thermo-cautery and argenti nitras. On October 19th the patient was dismissed strong and well. Köhler considers that resection is preferable to colotomy in all cases where the disease has not extensively involved neighboring structures, or where the patient's strength is not so reduced that this severe operation cannot be safely performed. Von Erckelen's researches show that life was prolonged in 62 per cent. of the published cases of colotomy; but, of course, the focus of disease was not thereby removed, and there was no thought of a radical cure. Such a cure is, however, much more likely after extirpation, for the growth rarely infects the lymphatic glands, and is but little prone to metastatic formation or recurrence. Besides, this method renders the objectionable artificial anus unnecessary. Up to the present time eighteen out of twenty-five cases of completed resection of the large intestine have taken a favorable course. In three of these the disease has recurred with a fatal result; but the remaining fifteen, *i. e.* sixty per cent. of all those operated upon, seem to be perfectly cured. As regards operative details, Köhler recommends that the abdominal incision be made in the linea alba, arrest of hemorrhage being thus facilitated and a good view of the parts obtained. During the operation the divided end of the intestine is to be kept closed by the hand of an assistant, while, if possible, the piece to be resected and the adjacent healthy part are drawn beyond the abdominal wall, so that an escape of intestinal contents may not take place into the peritoneal cavity. Finally, he recommends that, as in the case above described, the sutured intestine should be fixed opposite the lower end of the wound in the abdomen.

Crural Neuralgia Among Dentists.

Dr. J. B. Sutton makes the following curious observation in the *Lancet*:—

On June 20th I was called to a gentleman said to be suffering severely from sciatica. The patient was resting on his right side, complaining of intense pain in the left loin, radiating thence along the outer and anterior aspect of the left thigh whenever he attempted to move. Firm pressure, applied between tuberosity of ischium and great trochanter of femur was painless, but the instant one touched the skin immediately over the erector spinæ muscle severe pain was evoked, extending down the thigh to the knee-joint, mapping out exactly the course of the anterior crural and external cutaneous nerves. Pressure over the points of exit of the second, third and fourth lumbar nerves from the spinal canal caused excessive pain. The nerves at fault were clearly the second, third and fourth lumbar, the hyperæsthetic area in the loin clearly corresponding to the distribution of the posterior divisions of these nerve trunks. The case was obviously not one of sciatica, but crural neuralgia, having a very unusual distribution; the ordinary forms of this disease extend to the foot and toes of the affected leg. Belladonna and aconite were applied locally, strychnia internally; the patient was convalescent in seven days.

Two days later a similar case came under my notice, and a third has been reported to me with exactly similar symptoms. Curiously enough, the three patients were dentists, engaged in the active duties of their profession. It appears exceedingly probable that this painful affection may be explained by the fact that when dentists operate they always stand at the right side of the patient, consequently, when manipulating cavities in teeth difficult of access it is necessary to throw themselves into a constrained attitude, whereby the lumbar vertebræ are slightly flexed anteriorly, but flexed laterally to a considerable degree. It is necessary, sometimes, to maintain this cramped position for long periods, the temporary distortion being even more exaggerated when the dental engine is being used. These combined flexions cause the lumbar nerves to become congested, irritated, and possibly injuriously nipped as they pass through the intervertebral foramina, thus giving rise to the symptoms detailed above.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received a corrected copy of the address entitled "The Genius of Medicine," which we noticed some time since.

——It is always elevating, instructive and entertaining to read the lives of great and good men. No better reading can be placed in the hands of the young and growing generation than the records of the trials and achievements of the good men who have gone before. Thus do we feel when we read the "Life of John M. Briggs, of Bowling Green, Ky.," by W. K. Bowling, M.D., which we have received in the form of a reprint from the Nashville *Journal of Medicine and Surgery*, July, 1882.

——Dr. John M. Keating, of Philadelphia, has added to our knowledge of the parasitical nature of disease, by the discovery of micrococci in the blood of malignant measles. He failed to find them in ordinary, simple cases. Noting that alcohol most readily checked the develop-

ment of micrococci in culture solutions obtained from erysipelas, diphtheria, etc., whisky was relied on as the sheet anchor in the treatment of these cases, with most gratifying results. His experience is set forth in full in a reprint from the Philadelphia *Medical Times* of June 7, 1882.

——"A Successful Ovariotomy in 1866," is the title of an article by Dr. Robert Newman, a reprint of which, from the *New England Medical Monthly*, we have received. Sixteen years ago ovariotomy was comparatively an unusual operation, and a successful case then possessed much interest to the pioneer physicians who were trespassing upon the hitherto dreaded and feared borders of peritoneal surgery; to-day successful ovariotomies are so common that they are accepted almost as ordinary operations, so that this report possesses more historical than practical interest.

——The "Transactions of the Medical Society of the State of Michigan," for the year 1882, contains very much of interest and value, notably the "History of two cases of mal-presentation," by Dr. E. P. Christian, of Wyandotte; "Optic Neuritis," by Dr. Leartus Connor, of Detroit; "Antisepsis in the Treatment of Disease," by Dr. D. W. C. Wade, of Holly; and "Urinary Deposits," by Dr. Julius A. Post, of Lansing. All of the papers are very good, but in an especial manner would we desire to call attention to the two following: "The Insanity of Masturbation," by Dr. C. B. Burr, of Pontiac; and "The Legal Responsibility of Surgeons for Ununited Fractures," by Dr. Foster Pratt, of Kalamazoo. Limited space prevents us giving any abstracts from them, but we should advise all interested in the subjects to procure and read them.

——"The Antiseptic Treatment of Wounds after Operations and Injuries," by W. T. Briggs, M.D., a reprint from the Nashville *Journal of Medicine and Surgery*, is a timely contribution to medical literature. In this day, when the father of asepticism is being doubted, his statements twisted and his conclusions denied, it is well that we should have a clear exposition of all that pertains to this very important subject. The author sums up the contents of his paper as follows:—

1st. The germ theory of wound infection is not established.

2d. The antiseptic treatment of wounds after operations and injuries is not limited to Listerism nor to any other special method, but is based upon broad, general principles.

3d. Antiseptic surgery embraces every condition or agent that tends to prevent putrefactive changes in wounds, or to remove or neutralize the effects of such changes when they have occurred.

4th. All wounds are healed by reparative inflammation.

5th. All wound accidents are the result, either directly or indirectly, of destructive inflammation.

6th. The antiseptic treatment of wounds, properly considered, consists, first, of such means as will restrain inflammatory action within reparative bounds; and second, of such means as will subdue excessive action and remove or neutralize the effects of destructive inflammation.

BOOK NOTICES.

A Treatise on the Practice of Medicine, or the Pathology and Therapeutics of Internal Diseases. By Alonzo B. Palmer, M.D., LL.D, etc. Vol. ii. New York: G. P. Putnam's Sons. 8vo. pp. 864. Price, cloth, $5.00.

The present volume of Dr. Palmer's *Practice* includes diseases of the respiratory organs, of the heart, of the urinary apparatus, of the brain and nervous system and parasitic diseases. It is written in his usual clear and forcible style, and although the arrangement is strictly didactic, it is possible to read a good deal that he writes without fatigue. Speaking from long personal observation, he has formed independent views of treatment, and as they have been the result of actual practice in our own country, they are vastly more worth regarding than those of foreign authors, or than that spurious article of home production which is derived from the perusal of foreign books, and an endeavor to apply their systems to this country.

Dr. Palmer takes occasion in this volume to reiterate his well known confidence that a full dose of quinine and opium will abort pneumonia, if administered in the early stage. He considers it safer and surer than blood-letting, and without the possible dangers of the latter.

The question of the use of alcohol as a prophylactic in phthisis is discussed at length and answered in the negative. But the discussion does not seem to us wholly ingenuous. Nobody claims that drunkards, out-and-out sots, are particularly free from phthisis. Their exposures are too numerous and reckless. Yet this is the class that Dr. Palmer seems to have in his eye. The contention of the affirmative is that the moderate and regular use of alcohol is a preventive. This he does not fairly meet.

In cases of insolation he recommends cold water and morphine. He also speaks well of quinine. The mortality he places as high as 40 or 50 per cent. This is only true of the severe cases during extreme heat in the great cities. In country districts it is much less.

We have no doubt Dr. Palmer's work will be well received by the profession. It is judiciously prepared and fully merits a good share of popularity.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

HINTS CONCERNING MEDICAL LEGISLATION.

At the various meetings of medical societies during the summer months suggestions for medical legislation are brought before the profession, and these are usually referred to a committee for action during the winter, when the Assemblies of the different States are in session. Medical bills for the regulation of the profession itself and for the establishment of Boards of Health should be introduced into the Legislature of every State where such acts are not already in force. It is nothing less than a disgrace to any Commonwealth not to have these acts on its statute books.

There is, however, an extraordinary apathy among Assemblymen as to any bill concerning doctors or the public health. They suspect either that such bills spring from the rivalry of schools of practice, or else that their chief object is "to give some doctor a job." They are slow to recognize the fact that a doctor honestly desires an improvement in the general health of a community. They ask how it is that he wants to cut down his business in that way, and they are incredulous when they are told that it is a purpose of the physician's life to prevent people falling ill.

Another cause of their lethargy is that necessarily such bills have "nothing in them," as the legislative phrase is, which means that they involve no monied interest, and that there is no cash to be paid out for "log-rolling."

These difficulties stand in the way of all medical legislation, and consequently it is no easy matter to carry a bill through the two houses. While not often actually opposed, there is a vast *vis inertiæ* to be overcome, and it is worth while to consider carefully how best to accomplish this.

It is, of course, easy to have any bill presented and referred. The struggle is first in the Committee and next in the House. Those who have the bill in charge will, it is presumed, be carefully prepared to state to the Committee its merits, and the urgency of its adoption. They can generally have it called up by persistently boring the chairman, or by securing any member of the committee as an earnest advocate of it. The objections and questions of the other members can generally be foreseen and readily answered. A physician speaks with a certain degree of authority on matters relating to his own vocation, and it is rare that a Committee, if fairly satisfied, decline to report such a bill favorably.

The real struggle is in the House, and for this the preparation must be made far in advance. As politicians say, we must there "fish with a long pole." As soon as a medical society has decided to apply for legislation, the persons who are appointed to work for it should print the proposed bill in full, and *write* to one or more leading physicians in every legislative district of the State to interview their representative, and explain the bill to him. We say *write* to these physicians, because a *printed* request of that kind is waste paper. It is considerable trouble for a busy practitioner to interview a politician, and to ask such aid as that deserves a written letter.

It should be particularly requested, in that

letter, that prospective opposition be reported, and the criticisms of the bill be mentioned.

In this manner, nearly every member of the legislature will know what the bill is, and, moreover, he will know, from home authority, in whom he can trust, that it is an honest and a useful measure.

It may be said that this entails a great deal of work. So it does. So does success anywhere. The man who thinks the game will not pay for the candle, is not the man to be put in charge of the measure. And if no man is found ready to take pains to conduct the affair rightly, the matter had better be dropped until such a hero appears.

The chief reasons of the failure of a medical bill are either that the instrument is badly drawn, or that those who have it in charge trust to its intrinsic merits, and do not take the trouble to smooth the road for its adoption.

DISGUISED SYPHILIS.

Every wide-awake physician who desires to be successful in his warfare against disease, must ever be on his guard, and be always on the lookout for what we call disguised syphilis. We mean *disguised* on account of the moral character of the patient. It will be wrong, and many an innocent person will be unjustly condemned and improperly treated if the general practitioner views all his patients through the venereal spectacles of the professional syphilologist. We do not mean to advise this; far from it. But what we do desire is to call attention to the well known fact that syphilis is capable of transmission from one to another in many other ways than by sexual intercourse, and that therefore the physician should be always on the lookout for it, in order that he may intelligently treat and cure it. That syphilis is curable, is also now a pretty generally accepted belief. Again, there are few diseases that present to us such a variety of symptoms, and that are, therefore, so likely to be confounded with other diseased conditions. To make our advice clear we will relate a case from actual life.

A married lady, of altogether unimpeachable character, whose husband enjoyed the same distinction beyond the slightest possibility of doubt, and who had been married ten years, and given birth to three splendid children, is the central figure in our story. She was about two months pregnant when she received into her family a young female relative, who had been brought up in Germany (where, if rumor be true, and this girl's statement can be relied upon, morality must be at a very low ebb), and, whose mother having died, was, for some months before coming to America, her own mistress. She was naturally a vain, precocious girl, with lax ideas of modesty and morality, though there was not in her behavior sufficient grounds for accusing her of indulgence in sinful pleasures. Soon after her entrance into this family a lupus-like eruption occurred on her scalp, which she said she must have caught on shipboard, and added "that it was nothing; that *nearly every one* in Germany had it." Her head was in a frightful condition, and this good lady, in her charity, undertook to wash and dress it, having no suspicion of the risk she incurred, for we verily believe that she had never even heard of such a word as syphilis.

For a time all went well. After a few weeks this lady noticed that a *pin scratch* on her finger, instead of healing, became inflamed and angry looking, and in a short time a nut-like swelling appeared on the inner aspect of the elbow. She began to lose flesh, her appetite failed, her *throat became sore*, she became nervous, sleepless, and suffered from headache, became short of breath, suffered from palpitation of the heart and great weakness, and albumen and phosphates appeared in the urine. Her condition, so much more terrible than in any previous pregnancy, alarmed her, and she sought medical advice. She told her physician the history we have given, and stated that she herself thought she had been exposed to *blood poisoning*, that convenient and indefinite pathological condition. The doctor had some suspicion that she might be suffering from syphilis, but owing to her pregnancy was fearful to prescribe specifics, and so contented himself with ordering tonic treatment. She grew daily worse,

until fears were entertained for her sanity, so dreadfully exhausted was her nervous system. It was then resolved to resort to anti-syphilitic treatment. It had now been five months since she was inoculated. Biniodide of mercury ($\frac{1}{8}$ gr. doses) and iodide of potassium (10 grs.) thrice daily, were ordered. Scarcely had she begun this treatment when she commenced to improve, and after two weeks she was like a different woman. She was then put upon tonic treatment, and in three weeks from the beginning of the specifics she expressed herself as well; she had neither ache nor pain, appetite enormous and sleep excellent and refreshing, thus clearly demonstrating the nature of the *blood poisoning*.

You now know what we mean by *disguised syphilis*. There was no earthly reason to suspect this lady of having the disease, except the two facts, 1st, of her occupation when she was taken sick, and, 2d, that she did not improve under what seemed appropriate treatment. When carefully watched mercury is not a dangerous drug; therefore, whenever you have good ground to suspect disguised syphilis do not fear to use it, but be very sure that your grounds for suspicion are good. Remember, as we have said, that syphilis is capable of transmission in innumerable ways, and that therefore you are likely to encounter it in the most unlikely persons. Whenever you meet a case that presents any of the symptoms of syphilis, no matter how irregular or obscure they may be, if you cannot account for them in any other way, let your suspicions be directed toward syphilis, and by using judgment endeavor to make an accurate opinion, without allowing the patient to have any idea of your suspicion. By neglecting this last advice you may entail a lifetime of misery on those who do not deserve it. The lady of whom we have told you has not the slightest suspicion of the true nature of her disease, thank God, and neither has her husband. Therefore, again we advise you, be ever *prudently* on the watch for disguised syphilis, and we warrant that you will find it oftener than you now dream of, and that many obstinate cases which have caused you to fret and worry will recover like magic.

COUNTER-IRRITATION.

Of all therapeutic measures, there is probably no single one so universal, and so potent in its application, as counter-irritation. The disputed point, as to whether it produces its results through the agency of the nervous or the circulatory system, has no practical interest for the busy physician. He has but little time for theories or physiological experimentation, what he most desires are facts and results. In counter-irritation he has them both; it *can* cure, and it *does* cure. It matters but little in kind, but greatly in degree, what counter-irritant is used. When we desire a profound impression, as in the initial stage of asthenic pleurisy, nothing short of a fly blister, and a big one at that, one that will cover the whole affected side, will do any good. A mustard plaster, under such circumstances, will be like a child playing at war, as compared with real battle. Whereas, when we meet an asthenic type of the same disease in a weakly and debilitated individual, the violent fly blister would be too powerful, and resort must be had to the gentler mustard. Much undeserved odium has been cast upon counter-irritation, as upon many other therapeutic measures, because of inferiority in quality of the article used. We have used half an ounce of cantharidal collodion with the result of merely soiling the part to which it was applied, it did not even *redden* the skin, while half a drachm of a good article, applied to the same part, on the same person, blistered most terribly.

Many object to counter-irritation of a severe character, on the ground that it produces an external sore that is sometimes very hard to heal. That this is true no one can doubt. It does sometimes happen that very tedious and painful abrasions of the skin, or sores, do result from fly blisters or tincture of iodine, or some other equally powerful counter-irritant. But these are the exceptions, and ought not to militate against the rule, which is, that this form of treatment is an exceedingly valuable one in nearly all affections of an inflammatory nature. A large volume could be written on the different counter-irritants and the great value of counter-irritation, but it is

not our purpose to do more than merely call your attention to the matter. Every physician must wisely judge what cases are suitable for this form of treatment and what articles are appropriate to the effect desired. But remember, that while it will be all very well to resort to internal medication, counter-irritation *can do no serious* harm, and it will oftentimes amazingly aid the action of your drugs.

Notes and Comments.

The Contagiousness of Pulmonary Consumption.

Dr. Herbert Davies, consulting physician to the London Hospital, and to the Royal Hospital for Diseases of the Chest, writes to a recent number of the *British Medical Journal*, giving some stror g arguments against the contagious properties of pulmonary consumption. He quotes from a letter, written in 1867, by Mr. Edwards (resident medical officer of the Brompton Hospital for seventeen years), to Dr. R. Payne Cotton, in which he says that he remembers fifty-nine resident medical assistants, whose duration of office has averaged six months, all but two of whom are living, one dying from aneurism, and the other from some unknown cause. The present chaplain has held office for seventeen years, and his two predecessors are living. The matron has been resident for more than sixteen years, and the two former matrons are living. Of the nurses now in residence, one has been here 24 years; two, 12 years; one, eight years, one 7, one 6½, and one 5 years. No under-nurse has died of phthisis. The head nurses sleep each in a room containing fifty patients, and two only are known to have died—one from apoplexy; and one, some time after she had left the hospital, and after an unhappy married life, of phthisis. All but two of the physicians who have attended the in and out-patients during seventeen years are living. One died from causes unknown, the other from causes unconnected with diseases of the lung.

Intestinal Obstruction Relieved by Puncture of Bowel.

Dr. James C. Worthington reports, in the *British Medical Journal*, the case of a man, age 28, who had been seized, two days before his admission into the hospital, with agonizing pains in the region of the navel, accompanied with sickness, which became stercoraceous the next day. Opium afforded a little relief. He took a strong purgative draught, which was followed by sudden increase of pain and stercoraceous vomiting. Upon admission he lay on his back, with both legs drawn up, tossing from side to side, countenance pale and anxious, tongue coated, skin clammy. Had passed no urine since previous day. Pulse 76, Temp. 99.8°. Laudanum in large doses, and a few sniffs of chloroform, gave temporary relief. Three pints of warm water was injected into the bowel. Some of it was retained, and that which returned was hardly discolored, and contained but a few floating bits of hard fæces. Warm fomentations were applied, and laudanum, q. s. to control pain, ordered. The next day he passed a small amount of highly concentrated urine. No return of sickness. Four days afterwards he seem ed so much worse that it was decided to puncture the bowel at a point where it was much distended and tympanitic. A medium sized aspirating needle was introduced, which let off a large quantity of flatus, with immediate relief. After a while fluid, similar to that vomited, began to escape through the tube, which was kept in position for half an hour. It was then rapidly withdrawn, and lint, plaster and a bandage applied. The patient at once said he felt greatly relieved. In the evening the temperature rose to 100.2°. During the night he had two fluid stools. He made an uninterrupted recovery, and when discharged, a week afterwards, a small, indirect inguinal hernia, on the right side, showed itself, for the first time.

Resorption in the Stomach.

Dr. H. Tappeiner has communicated to the *Zeitsch. f. Biolog.*, xvi, p. 497, the result of his experiments on dogs, etc., regarding the power of resorption exercised by the stomach. He put a ligature around the pylorus, and introduced through an œsophagus-tube solutions, the contents of which quantitatively and qualitatively were known. He found that of watery solutions of glucose, sulphate of sodium, taurin, peptone, and strychnia very little was resorbed.

But if he took alcoholic solutions, the result was quite a different one. Far more was absorbed than left in the stomach, and while, for instance, the effect of a watery solution of strychnia became only very gradually apparent, and in a mild degree, the same quantity of strychnia in an alcoholic solution, caused, within ten minutes, the death of the animal.

The effect was, however, not uniform, and he observed that the rapidity and the quantity in

these absorption processes depended, to a great degree, upon the quantity of fluid previously in the stomach. With the pylorus closed, watery solutions of chloral had very little effect, while alcoholic solution caused sleep within a few minutes. Of the alcohol, always three-fourths was absorbed.

This gives us an indication for the diet of persons suffering from cancer of the pylorus, or of induration and narrowing of this orifice, due to other morbid leisons. The nutritive material should be given in alcoholic solutions, and very little at a time, so that there is never much fluid at any one time in the stomach, and, for that matter, very little solid material also. All medicines, in such cases, should be administered, dissolved in alcohol.

Some Observations on Consumption.

Dr. William H. Pearse, in the course of some observations in the *Medical Times and Gazette*, says that he is being continually struck with the phenomenon that in the phthisical, the upper maxillary and nasal bones have an exaggerated tendency to one or the other side. In twenty-four cases to the left and in thirty four to the right. Where the obliquity was to the right, the right lung was diseased in sixteen cases, the left lung in eighteen. In those in which both lungs were diseased four had the obliquity to the right and one to the left side. He does not offer an explanation.

He has often noticed, among the poorer classes who are phthisical, a flattening of the face across the root of the nose. One tall young woman with infraclavicular regions much sunken, and who has been under observation during two years, but in whose lungs no disease can be traced, has a prognothic face, with teeth of negro type.

Sometimes the end of the nose is lumpy in proportion to the organ; in others, abnormally pointed; in others the terminal cartilages are large and unsymmetrical. He has on many occasions been able to predicate phthisis from the unsymmetrical and rather large terminal cartilages of the nose.

Often in the phthisical the head and neck are not well set up, but the neck, leaning somewhat forward, is at the same time sunk down, as it were, between the shoulders.

Correlation exists between the hands and phthisis; while some have exquisitely fine hands, a large proportion have unduly large hands. One may often predicate phthisis from the large and cold hands.

The body in some cases will develop into that of a fine young man or woman, the thorax remaining that of a child.

Syphilis Conveyed by Skin-Grafts.

The *Lancet* says that another case in which syphilis was conveyed by skin grafts is reported in Paris, by M. Féréol. It occurred in the practice of M. Deubel; the patient was a man, aged forty-nine, who had not had any venereal affection, and who had a large wound caused by erysipelas, with sloughing. Seventy-five dermo-epidermic grafts were put on, nearly all of which "took," and cicatrization was rapidly effected. A month after the application of the first grafts the cicatrix began to ulcerate in several places. Six weeks later an abundant roseolous eruption broke out over the body, and a month later mucous patches appeared in the mouth. One of the sons of the man, who had furnished grafts on each occasion, then consulted M. Deubel for mucous patches about the anus, and stated that eighteen months previously he had had a hard chancre, for which he had not had any treatment. The case is apparently beyond all doubt, and shows the necessity for caution in the selection of persons from whom grafts are taken. The safest rule to follow is, wherever possible, to take the grafts from the person on whom they are to be implanted.

Elephantiasis of the Vulva.

The following interesting case, which occurred in the Goculdas Tejpal Hospital, has been recorded in the *Lancet*:—

A Hindoo woman, aged thirty years, presented a most unsightly elephantoid tumor in the left labium, which extended downward into the perineum. In the right labium there was a smaller tumor, about the size of an orange and unconnected with the first. The incision to remove the tumor on the left side extended from the mons Veneris to the end of the perineum, and was carried on the inner side through the mucous membrane on the inner surface of the labium. The incision on the outer side extended to the left groin and margin of the thigh; and when the mass, which weighed about five pounds, was removed, a most unsightly gaping wound was left There was very little hemorrhage, and slight torsion was found sufficient to arrest that in the three small vessels severed. The smaller tumor on the right was now removed, and the edges of the wound were brought together without any trouble. To effect healing of the first

wound the legs had to be brought together and the thighs tied firmly by a broad bandage. Three or four wire sutures were put in, by which the mucous membrane of the vagina and the outer integument were connected. This position, however, was more relied on to assist the healing process than anything else, and she was so kept, with the legs tied together, for over three weeks. It was most remarkable how the parts began to assume their natural shape as the healing process went on. The surface had altogether healed over five weeks after the operation, when the patient was removed by her husband.

Rider's Sprain.

In the *Lancet*, Dr. Henry A. Morris calls attention to a form of accident which is commonly found among riders, and which consists in a rupture of some of the fibres of one of the adductor muscles, generally the adductor longus. The accident generally happens to hunting men, is more frequent in tall men, and affects the right thigh more frequently than the left. It is usually caused by the horseman suddenly making a strong grip, owing to his horse rearing, shying, slipping, or unexpectedly taking a jump, by which means the adductors are suddenly brought into forcible action. The pain at the time is often trivial, not causing the horseman to dismount; but subsequently more pain is felt in walking; rather severe pain attends the act of mounting, and unbearable pain is caused by gripping the horse. Time and rest will, of course, cure the greater number of these cases, but, in addition, a broad elastic bandage firmly applied over the upper part of the thigh, and secured by a figure-of 8 turn round the waist is of every material assistance at first, in locomotion.

Hydronephrosis, Abscess.

In a woman, aged sixty, a tumor of the size of a child's head was at different times observed to reappear and disappear in the right side of the abdomen. The case is reported by Dr. Landau, in the *Arch. f. Klin. Chirurg.*, xxvi, p. 776. A trial-puncture was first made; the fluid discharged was found to be rich in cholesterin. A second one resulted differently, as now in the fluid were noted, besides a large quantity of urea, traces of uric acid. The fluid the second time was opaque. The radical operation was then made, and it was observed, that besides the pyonephrosis, into which (on account of want of antiseptic precautions?) the original hydronephrosis had been changed, there existed a perinephritic abscess, which had to be opened and so brought in direct communication with the wound in the kidney, the latter certainly being a floating one. The final result, however, was favorable; undoubtedly better than when, under these circumstances, the floating kidney should have been extirpated.

In connection with this we wish to draw the attention of our readers to the deplorable negligence with which often a trocar is used. We read, that occasionally after paracentesis peritonitis has followed; that a pleuritic serous exudation after thoracentesis changed into empyema, and that even the tapping of a hydrocele brought on an attack of erysipelas. If the trocar in these cases had been examined, it would have been found full of bacteria. Such an instrument should be placed for ten minutes at least in a carbolic acid solution (gr. vj to ℥j water, never oil or alcohol, as that gives an inert fluid), and the whole procedure should be made, as much as possible, under antiseptic precautions. Then such accidents as the above cannot happen.

Treatment of Obstinate Vomiting.

In the course of an article on this subject, in the Boston *Medical and Surgical Journal*, Dr. S. G. Webber says: Often the best method of treating this complication is to give the stomach rest. Sometimes only a large amount of food taken at one time excites vomiting: then it is sufficient to resort to frequent feeding, giving a very small quantity each time, a mouthful, or a spoonful every fifteen or thirty minutes; thus the stomach never contains a large mass of food requiring considerable muscular exertion to roll it about, and by its weight or bulk exciting the reflex irritability of the nerve centres. Many times, however, this is not enough; the stomach requires more complete rest, and the best treatment is to withhold all food and medicine; sometimes a few hours' rest is enough, again it requires two or three days; then it will be necessary to use nutrient enemata. Where there has been much vomiting thirst may be very annoying to the patient; small lumps of ice held in the mouth will relieve this, and generally do not cause vomiting. After the stomach has had sufficient rest it is best to commence feeding by the mouth, with caution, giving a little frequently. Milk and lime water, equal parts, a teaspoonful every half hour, should be first tried; if well borne the amount can be increased gradually. It is a mistake to increase the quantity too rapidly.

Precautions against Puerperal Fever.

Dr. H. G. Sworn writes to the *Lancet* as follows:—

On July 31st, I was called to see the child of Mrs. M. On arrival I found the child suffering from scarlet fever. At the same time I was requested to see an aunt of the child, who was ill, and whom I found suffering from scarlet fever also. Noticing that the mother was pregnant, and to all appearances in an advanced stage, I strongly advised the immediate removal of both the patients. The mother, however, would not hear of the child being removed, but allowed her sister to be taken to the hospital, where she remains at the present time, having had a severe attack, her throat being much affected. The child subsequently skinned very freely. On August 5th the mother was taken with labor pains, and was delivered of a child at 6 P.M., in the same room in which the child was, there being no other room in which to isolate the case. I had the woman placed between sheets impregnated with carbolic acid as soon as labor set in; and in place of using lard to lubricate the fingers for making examinations, carbolized oil was employed. All the napkins used then and subsequently were saturated with the same. The case progressed favorably, no bad symptoms intervening. It would be interesting to hear more on this subject.

Night Terrors in Children.

In a thesis presented before the Paris Faculty in 1881, M. Debacker follows M. Lasègue's classification, and divides the nocturnal hallucinations of children into two grand classes: hallucinations of non-cerebral origin, and hallucinations of cerebral origin. The first, occurring only during a short period of time, and not of gravity, depend oftenest on gastro-intestinal derangement, on indigestion, obstinate constipation, the presence of worms in the intestines, or on laborious dentition. In some cases they represent a form of delirium due to inanition in the period of convalescence from acute diseases, or in the exhausted condition induced by excessive fatigue, masturbation, or some chronic affections.

They are in other cases produced by the action of toxic agents, such as alcohol, lead, belladonna, etc.; or by other diverse causes: fear at being alone in the dark, terrifying stories, or even by the irritation induced by prurigo, the itch, or the presence of pediculi.

The grave and persistent hallucinations of cerebral origin depend, 1st, on brain affections to come, such as tuberculous meningitis, chronic hydrocephalus, idiocy, epilepsy, etc.; 2d, on cerebral troubles already present, as idiocy, delirium of persecutions, and dementia of childhood. The author cites numerous examples of the diverse forms of hallucinations he mentions.

Unity of Poison in Scarlet Fever, Etc.

In the Glasgow *Medical Journal*, for August, 1882, Dr. G. De Gorrequer Griffith publishes a lengthy, interesting and logical article on the unity of poison in scarlet, typhoid and puerperal fevers, diphtheria, sore throats and certain allied ailments, and many other affections heretofore usually considered to be separate and entirely distinct diseases. Numerous illustrations are given, like the following: "I have seen cases intermediate between scarlatina and variola, and have known diphtheria in children give rise to scarlatina in the mother." The whole substance of his theory can be summed up in his closing paragraph: "I have many other affirmative proofs and expressions of opinion which I will not here quote, and will conclude with this axiom: 'by unity of poison is meant not that the poison is always the same; but that the one poison—the one *origo mali*—whatever it may be, will originate several so-called different affections.'"

Double Suicides.

In a recent issue, the *Lancet* assumes that where two persons conspire together to kill each other, or to destroy their several lives simultaneously, it is simply absurd to suppose that they are insane. In making this statement, they are not unmindful of the cases of double insanity and double suicide that have been recorded, but consider that a closer scrutiny would result in classifying them as instances of murder and suicide.

Facial Spasm (Tic convulsif).

Dr. M. Bernhardt reports, in the *Zeitschr. f. Klin. Med.*, III, 1, a number of cases of spasm of the facial nerve and its branches—tic convulsif—and remarks that, with the exception of a few cases, in which it was increased, the electric excitability of the nerves as well as of the muscles of the affected side of the face were found by him to be normal. All electro therapeutic applications, even the method recently recommended by Berger (*Centralbl.*, 1880, p. 314), the application of the anode of a moderately strong, constant current over the temporal bone

of the side opposite the seat of the affection, cause very little improvement, if any. In the two cases in whom the nerve has been stretched, relapses occurred. Subsequently, in one of the cases, the patient had to be cured of paralysis following the stretching. Bernhardt cautions against further mutilation of the motor nerve, as contractions, spasms and choreic motions were almost a physiological occurrence after grave rheumatic or traumatic paralysis of the facial nerve, and that nobody should be astonished, therefore, if after artificially produced palsy during the process of regeneration the same symptoms made their appearance.

Excision of the Pylorus.

The *Medical Times and Gazette* says that Dr. Van Kleef, of the Hospital de Calvaire, Mæstricht, relates, in the *Presse Méd. Belge*, July 23, the case of a woman, aged thirty-seven, upon whom he performed excision of the pylorus on account of stenosis, supervening on ulcer of the stomach attended with severe hæmatemesis. She had become greatly reduced in strength, and for some time past had been fed by the rectum. The indurated pylorus, when removed, measured 4½ by 5 centimeters, and a quill could scarcely be introduced into its aperture. The stenosis was due to cicatricial tissue, no sign of carcinoma being present. The operation lasted two hours, and an hour or two elapsed before the patient began to awake from the anæsthetic condition. Her recovery from the state of anæmia was slow but progressive, and two months after the operation she was able to leave the hospital, weighing 39 kilograms. At the date of the report, about six months after the operation, she weighed 45 kilos.

Tuberculosis.

Dr. Kammerer, Imperial Health Officer to the city of Vienna, has published an important address to the magistrates of that city on the dangers which threaten the health and life of the population, through animals affected with tuberculosis. The victims are insidiously struck down, says Dr. Kammerer, through two of the most important articles of daily diet—milk and meat. The milk of cows with tuberculosis acts as an unconscious inoculation upon adults and children who partake of it, and in the case of the latter, the seed of tuberculosis is being imperceptibly sown among thousands in the great towns. Dr. Kammerer regards infection by this channel as being quite as fruitful a source of the disease among the young as hereditary taint, to which it is usually traced. He regards it as exceedingly doubtful whether boiling or roasting ever can effectually eradicate the germs of infection from the flesh of tuberculous animals.

Treatment of Angina Pectoris.

According to the *Medical Press and Circular*, Dr. A. Mühlberger, of Herrenalt, believes that in concussion we have an excellent means of keeping in check the violence and duration of the sterno-cardiac attacks. He further notes that kneading and rubbing have long been tried and approved remedies against muscular cramp, and that as angina pectoris is nothing more or less than cramp of the cardiac muscle, it seemed to him likely a similar result would be obtained in parallel cases by the like means.

He finally sounds a note of not unheeded warning in the *Deutsch. Med. Zeitung*, against the too bold use of remedies in this affection, and we may add in others also, and recalls the case of an elderly medical man who was relieved of his angina only to die of the morphia that procured the relief.

Coca to Assuage Thirst.

Surgeon Major T. Edmonston Charles, M.D., of H.M. Indian Army, Honorary Surgeon to the Viceroy, writing in the *Medical Times and Gazette*, recommends, in the strongest terms, the chewing of coca *leaves* to relieve thirst when one is deprived of water. He speaks from considerable experience, and evidences no hesitation in expressing a very positive opinion. "It is the leaf alone that is a thirst-assuager, and no preparation of the drug should therefore be purchased to supplement the leaves. For other medicinal uses the wine may be secured, if thought desirable, but the elixir and other preparations in the market are nearly inert, and some of them contain noxious elements."

A National Medical and Sanitary Exhibition.

The advantages of public comparison and competition are so well known, that we hope the projected national exhibition of medical and sanitary supplies will be successfully carried out. It is proposed to hold it somewhere next year, the precise place and time to be determined at the approaching meeting of the Sanitary Convention at Indianapolis, October 18th.

Such exhibitions have been held several times in Europe, of late years, in Frankfort on the Main, in Berlin and in London, and they have always been productive of decided benefit, both

to the profession, the public, and the business interests of manufacturers. The last mentioned are so large in this country, that we are sure an ample display can readily be obtained, and a decided impetus will thus be given to further studies in this important branch.

We trust that the Convention will take prompt and decided action in this matter.

Special Reports.

NO. X.—THERAPEUTIC PROGRESS.

(*Continued from page* 222.)

BROMIDE OF POTASSIUM IN DIABETES.

The *Medical Times and Gazette* says that a member of the Académie de Médecine recently read a paper on this subject. During the past six years he has treated fifteen cases. He ignored entirely the routine dietetic treatment, on the ground that the disease consists not in the presence of sugar in the urine, but in the disorder of the organism, which produces the sugar in excess. He observed, by chance, that a diabetic patient whom he was treating for another disease, and who was taking a drachm daily of bromide of potassium, improved very much. He then made experiments on rabbits, by producing artificial diabetes. Four grains of the drug injected into the veins caused the sugar to disappear. He has ever since used this drug with good results in this disease. Alkalies, iron, arsenic and quinine, according to their several indications, form part of the general treatment, as does also muscular exercise of all kinds.

HYDRATE OF CHLORAL IN CHOREA.

The same journal says that Dr. Bouchut's treatment, *par excellence*, of chorea consists in the administration of hydrate of chloral in large hypnotic doses, even for children. He orders for a child of six years thirty grains in *one dose*, the dose to be repeated every day, and increased, if necessary, to forty or even sixty grains. The effect of this dose is six or eight hours' profound sleep, during which the child does not stir. After a couple of days the disease abates, and in about a fortnight the cure is obtained.

CARBOLIC ACID FOR CARBUNCLES.

In the *Australian Medical Gazette*, Dr. Charles Taylor says that he has treated six typical cases of carbuncle, all on the neck, and in men in good physical condition. Into five of them, during the first three days of their existence, was injected pure carbolic acid. In the sixth case free incisions were made first. The result was that the five cases treated without incision rapidly recovered, and the other only closed in after dragging through the usual dilatory course of extensive sloughing and profuse suppuration. In those cases injected with carbolic acid the carbuncle appeared rapidly to put on altered and healthy action, laudable creamy pus was secreted, pain disappeared, and cases that would in all probability have lingered through two or three or more weeks of incision, pain, poulticing and suppuration, were happily terminated in a few days, leaving neither scar nor blemish behind. Dr. Taylor injects into the carbuncle, by means of a hypodermic syringe, five or six drops of pure fluid carbolic acid. He recommends the skin of the surrounding region to be smeared with oil or cerate, to protect it from the escharotic influence of any acid which may escape during the operation. He states that little or no pain is manifested when the acid enters the tumor. When the acid is discharged into the swollen part, the patient at once becomes comfortable, and experiences a glow of pleasing heat passing throughout it. The carbuncle either quickly "aborts," discharges a small quantity of pus, and ceases to trouble, or runs through a few days of active suppuration, secreting abundant and healthy pus, and speedily terminating. In all his cases he states that he has found one application of the acid sufficient, aided by the usual linseed-meal poultice, fomentation, and such constitutional remedies as the individual case may suggest, namely, active alterative aperients, quinine, iron, etc.

SULPHATE OF QUININE IN CORYZA.

Dr. N. Ffalliott states, in the *British Medical Journal* (*Canadian Jour. Med. Sci.*) that the inhalation of a spray of sulphate of quinine will cure in a few hours (twelve at the utmost) coryza or nasal catarrh, if taken at the onset. The solution may be made by dissolving four grains of sulphate of quinine in an ounce of water, with sufficient dilute sulphuric acid to effect solution. A hand-ball spray producer is used. In this connection, the *Monthly Review of Medicine and Pharmacy* recommends, for a common cold, five grains of quinine to be taken as soon as you begin to sneeze and suffer from a feeling of tightness in the nasal passages. Repeat the dose every six hours.

NITRITE OF AMYL IN INFANTILE CONVULSIONS.

The same journal, quoting from Dr. Bridger, in the *Lancet*, says that he has obtained good results from the use of nitrite of amyl in the following cases: 1. Convulsions resulting from an abscess in the tympanum; 2. From tubercular meningitis; 3 and 4. From dentition. One-

third of a minim in mucilage was applied to the child's nostrils every three hours.

CYANIDE OF MERCURY IN OCULAR SYPHILIS.

The London *Practitioner* quoting from *Le Progrès Méd*, says that M. Galezowski speaks highly of the value of subcutaneous injections of cyanide of mercury in treating certain syphilitic lesions of the ocular membranes. Atrophy or neuritis of the optic nerve and changes affecting the retina or choroid are often unsuccessfully treated by the ordinary specifics, and Fournier's albuminate of mercury is in such cases scarcely, if at all, more efficacious. It is, however, in such cases that the cyanide treatment has produced excellent results.

EMBLIC MYRABOLANS, A NEW LAXATIVE.

The *British Medical Journal* says:—

We have received from Mr. Martindale specimens of emblic myrabolans, recently imported from India. It is the fruit, preserved in sugar, of emblica officinalis, or phyllanthus emblica. It is a euphorbiaceous tree; and the fruit, which is about the size of an olive, or perhaps somewhat larger, contains a hard, angular seed. Several species of myrabolans were formerly used in medicine; and an old writer says "they restore youth, improve the complexion, the breath, and the perspiration, and impart joy and hilarity." It is not alleged that this particular species possesses these properties; but Dudd, in his *Hindu Materia Medica*, says that it is "cooling, refrigerant, diuretic, and laxative. It promotes the appetite, and acts as a tonic." We have tried it carefully in several cases of habitual constipation, and have no doubt that it is a valuable addition to our list of laxatives. It must be remembered that it is a natural fruit, and not an artificial preparation. It may be eaten at dinner or dessert, and it would be absurd to regard it as a medicine. It is most valuable for children.

ATROPINE AS A CAUSE OF GLAUCOMA.

The same journal says that atropine has of late years been so widely used in ophthalmic practice, both in the treatment of various painful affections, and also merely for the purpose of paralyzing the pupil to facilitate the estimation of errors of refraction, or an examination with the ophthalmoscope, that the warning afforded by Mr. Streatfeild's letter, in another column, and to be found also in a case read to the Ophthalmological Society by Mr. Snell, and reported in our number for July 15th, has not been sounded too soon. It thus appears, on the evidence of competent judges, that a strong solution of atropine, such as is the officinal solution of the *British Pharmacopœia*, is capable of producing glaucoma in some cases. A way out of the difficulty is afforded by Mr. Streatfeild, who points out that a solution very much weaker than that provided by the *Pharmacopœia* would suffice to produce sufficient mydriasis for all ordinary purposes. Dr. Ringer has, we believe, made some experiments on this subject, and has found that a dilatation of the pupil, lasting some hours, can be produced by a solution containing what a chemist would consider a mere trace of atropine. A solution formed by diluting the pharmacopœial "liquor" with two or three hundred times its bulk of water, would be sufficiently strong.

SALICINE FOR AFTER PAINS.

A writer in the same journal says: There are a number of cases which fall within the experience of every practitioner, where, directly after the expulsion of the placenta, violent after-pains set in, and continue for many hours, often for days, to the great annoyance and exhaustion of the patient; they have nothing to do with the clots in the uterus, as none are ever expelled, and they occur mostly to women of a highly nervous temperament, who frequently suffer from neuralgia at other times. I have found opium useless in these cases, even in large doses; but salicine has the effect of rapidly and completely stopping them. I carry half a dozen powders, of fifteen grains each, in my bag, and give one, dissolved in water, directly the pains commence; to be repeated every two hours till the pain ceases. After two doses, that result is generally accomplished, and I have never had to give more than forty-five grains.

IODOFORM IN PHTHISIS.

At a recent meeting of the Manchester Medical Society (*British Medical Journal*) Dr. Dreschfeld read a paper on the internal administration of iodoform in phthisis. Many pathologists having now for some time held the view that tuberculosis was an infectious disease, depending on the presence of micro-organisms (a view which had received strong support by Koch's important researches), and that tuberculosis, phthisis, and scrofulosis were closely allied, if not identical pathological processes, the author was led, guided by the excellent results obtained in the local treatment of scrofulous diseases by iodoform, to try the administration of this drug in phthisis. This experience extended over more than six months; and the results so far obtained were satisfactory. The iodoform was given in the form of inhalation, and internally in the form of pills (one grain per dose), mixed with creasote and dextrine. The best results were obtained in cases of incipient and acute phthisis; in chronic cases the results were less satisfactory; in a few cases of laryngeal phthisis, the local application of iodoform powder to the ulcerated surface of the larynx was followed by immediate relief, and clearing of the ulcer—without, however producing healing of the ulcers. The conclusions arrived at were these: 1. Iodoform is

well borne by the patient, without producing nausea or gastric irritation. 2. Owing to its anæsthetic properties, it relieves the irritation in the throat, and the cough, especially in incipient phthisis. 3. In some cases, it increased the digestive powers and appetite, and relieved the vomiting. 4. It reduces slightly the temperature in cases of phthisis with raised temperature. 5. In no case have any bad results followed the inhalation of iodoform. 6. Hæmoptysis forms no counter-indication for its administration (in some cases, hæmoptysis entirely disappeared on the administration of iodoform). 7. In incipient phthisis, iodoform seems to arrest the disease.

THE CURE OF LICHEN RUBER WITHOUT ARSENIC.

The London *Medical Record*, quoting from *Monatsb. für Prakt. Derm., No.* 1, 1882, says that Unna has succeeded in curing six cases of lichen ruber by an ointment containing perchloride of mercury and carbolic acid, without the internal administration of arsenic. His formula is: Ung. zinci benzoati, 500 grams; acidi carbolici, 20.0 grams (4 per cent.); hydrargyri perchloridi, 0.5 to 1 gram. Carbolic acid appeared in the urine on the second, and there was slight transitory depression on the third or fourth day of the treatment. The duration of the treatment was in proportion to the time the disease had lasted. Unna recommends this treatment in all severe cases of lichen ruber (acuminatus), which are attended with much itching and depression, as being the speediest means of procuring alleviation and cure.

CONVALLARINE—A NEW DIURETIC.

The *Lancet* says, that Professor Germain Sée has brought to the notice of the Academy of Medicine a new substance, which promises to be of great therapeutic value. It is an alkaloid extracted from the Convallaria majalis, or the lily of the valley. This new alkaloid has been discovered by Dr. Hardy, an eminent chemist, who also discovered the alkaloid from the jaborandi, to which he gave the name of "pilocarpine." Convallarine, the name of the new substance, has been experimented with by Professor Sée, at the Hôtel Dieu, in conjunction with Dr. Hardy, of which hospital the latter is the *chef du laboratoire.* Its therapeutic action is compared with that of digitalis, for which it may be with advantage substituted, as it has none of the inconveniences attributed to digitalis. Dr. Hardy was led to make researches with this plant, from the fact of its being generally used by the peasants of Russia, who employ the herb in dropsies, and in all cases requiring increased diuresis. According to Professor Sée, the convallarine is a powerful diuretic, and it has a marked influence on the contraction of the heart, which it regulates, while it lowers the pulse in a remarkable manner.

PELLETIERINE FOR TAPEWORM.

Dr. H. Wilfort, in the Cincinnati *Lancet and Clinic*, says that Mr. Tanret, of Troyes, the discoverer of pelletierine (the active principle of the bark of pomegranate root), has of late put this anthelmintic in such a palatable form that it is taken without repugnancy on the part of the patient. It is imported in liquid form, put up in small bottles (fifteen grams each), the contents of one of which constitutes a dose for an adult.

No subsequent dietetic measures are necessary, only omitting supper and breakfast before the following day when the medicine is to be taken. It causes no discomfort to the patient, and is quick in its action; in the last case the worm, with its head, was discharged in one hour and a half after the cathartic was administered. It has, in my hands, proved to be the safest and most reliable remedy yet used against tapeworm.

TINCTURE OF IODINE IN ERYSIPELAS.

Dr. Charles F. Hutchinson, in the *British Medical Journal*, says that one of the most remarkably rapid cures he has ever seen followed the application of the tincture of iodine to a case of idiopathic erysipelas of the head and face. The patient was a large, robust man, of very plethoric habit, a free liver, and in every way the type of man one would expect to have a violent attack of an inflammatory disease like erysipelas. Iron and the usual internal remedies had been administered, and when he first saw him he was unconscious, rambling, and thought by all to be *in extremis.* As no local application had been thoroughly tried, he suggested cutting away the hair and painting the scalp with tincture of iodine. At the same time, he increased the dose of iron, and added forty minims of spirit of chloroform to each dose. The effect was magical. On meeting the next day, for consultation, he found every symptom improved; the redness had subsided, the stiffness was nearly gone, and consciousnesss was returning. The next day he was out of all danger, and was soon convalescent. He never had any return of the disease.

He thinks the rapid cure in this case was entirely due to the iodine application, as from its very first application the local symptoms showed marked improvement. Certainly, in his experience, he has never seen so apparently a desperate case recover so soon.

SALICYLIC AND CARBOLIC ACIDS.

The *Lancet*, in a recent issue, says the comparative value of salicylic and carbolic acids given internally was the subject of a recent paper by M. Desplats, of Lille. Each has an analogous action as a febrifuge, and the well-known effect of salicylate of soda in acute rheumatism can be produced, in some cases at least, by carbolic acid, and the rectal administration of either may be substituted for that by the mouth when there are difficulties in giving it by the latter. Urinary disturbances are unimportant and quickly cease if the dose is lessened. Albuminuria is rare, and passes off if the drug is omitted for a short time. M. Desplats mentions, for instance, a case of phthisis, in which, on account of high fever, two injections were given daily for two months, each containing half a gram of carbolic acid, without any ill effect. In the discussion which followed at the Académie de Médecine, M. Dujardin-Beaumetz expressed the opinion that the free use of carbolic acid in injections entailed a considerable risk of pul monary congestion, and the opinion was corroborated by several other speakers.

SALICYLATED STARCH.

The same journal says that Kersch has recommended salicylated starch in the treatment of eczema. It is prepared by mixing starch gradually with salicylated alcohol of a strength of 2 per cent, allowing the starch to sink to the bottom, pouring off the supernatant liquid, squeezing the starch in muslin, and drying it at a temperature of 80° C. In treating eczema it is recommended that after the scales have been removed the patches should be dried with antiseptic cotton-wool, then moistened with a 2 per cent. solution of salicylic acid in alcohol, and afterwards covered with a thick layer of salicylated starch.

ACTION OF QUININE AND SALICYLIC ACID ON THE EAR.

The *Medical Press and Circular* says that Dr. Kirchener has studied the action of these two medicines upon the ear, in order to elucidate the question, still disputed, as to whether the noises in the ear are really to be attributed to congestion of the labyrinth. Clinical experience has for a long time shown that these agents produced vertigo and a certain degree of deafness, which disappeared immediately on the cessation of the drug; but sometimes when the quinine or salicylic acid were given in large doses these symptoms persisted and constituted a long and serious affection. Experiments on animals proved that quinine and salicylic acid produced hyperæmia of the tympanum, and when excessive, hemorrhage might result. If the hyperæmia lasted a certain time it might cause an alteration of the ultimate ramifications of the nerve.

CHINOIDINE.

Dr. D. B. Bunn, in the *Clinical Brief*, says that chinoidine is a tonic and antiperiodic worthy of more frequent use than is generally made of it. To find a solvent for purified chinoidine, except alcohol, was a trouble to me for some time, until I tried citric acid solution. A little less than one ounce of citric acid in four ounces of water will dissolve one ounce of chinoidine, which is mixable in any proportion with glycerine, syrup, spirits or water. Chinoidine possesses more tonic and antiperiodic properties than are usually ascribed to it, and being cheap, it comes to be a worthy help for country doctors, for whom this article is written. Country doctors furnish medicines, advice and attention on the pay-next-fall plan, and generally take promises for pay in the end, for when fall comes a neighbor delights the doctor with the astonishing intelligence that his former patient is working on the railroad in Texas.

THE TOPICAL USES OF TANNIC ACID.

Dr. G. A. Parsons, in the same journal, says that in all cases of cutaneous capillary hyperæmia, or the subcutaneous cellular transudations, the topical use of—

℞. Tannin, ℥ ss
Glycerine, ℥ j M.

Triturate until perfect solution is effected. is very satisfactory.

In the first or hyperæmic stage of abscess, or risings, as they are familiarly called, the persistent application of a saturated solution of tannin in alcohol will, in a very large majority of cases, abort the pending abscess and restore the part to a healthy condition without ever reaching the stage of suppuration.

In indolent ulcers, and all unhealthy sores, I have yet to find a remedy that meets the indication better than a triturated mixture of tannin and vaseline. In the different erythema, tannin is almost always the base of my prescriptions. In quite a number of cases of erysipelas, both simple and complicated, I have used tannin, either the glycerinic or alcoholic solution, with the most gratifying results. I never "paint erysipelas with iodine," as was formerly the practice. In subcutaneous cellular thickening and induration, the remedy of remedies is tano-iodine ointment, made with—

℞. Tannin,
Iodine,
Vaseline, aa., q.s. M.

In diarrhœa due to relaxation of the intestinal mucous membrane, as well as the early stages of dysentery, tannin often acts charmingly well through local action on the disordered membrane. While it is true that a portion of the tannic acid given internally is converted into gallic acid, and produces its physiological effect upon the system through the medium of the circulation, it is nevertheless true that no inconsid erable portion, when given in large doses, passes through the intestinal tract unchanged, as a residuum from the stomach, and thus comes in direct contact with the morbid parts, and pro duces its characteristic constringent effect through an altogether local action.

IODOFORM IN DIABETES.

The *Medical Press and Circular* says that Professor Moleschott, of Rome, has published a series of articles in the last numbers of the *Wien Med. Wochensch.*, on the use of iodoform in the treatment of diabetes mellitus. For some months together he kept a series of five patients suffering from this disease under treatment by the drug, and from the results obtained came to the conclusion that iodoform was a drug that promised much in this affection, inasmuch as under its employment for a few days or weeks the sugar disappeared. In those cases that were not cured the sugar reappeared on the discontinuance of the employment of the iodoform, to disappear again when its use was resumed in increasing doses. It further promised much as the improvement set in, even when the use of starchy food was not limited, and even when the patient had to contend with exciting cares and excessive labor. A cure was effected in one case that had withstood the action of salicylate of soda. He recommends iodoform, gr. xv, extr. lactuc. sat., gr. xv, "cumarin" 1·15, to be made into twenty pills, of which one may be taken from twice to eight times a day.

Correspondence.

A War Relic.

Ed. Med. and Surg. Reporter:—

On the 28th of August a man came to me with an abscess on his left buttock, which had been lanced by another physician about five weeks previously, and since then had kept on discharging large quantities of pus, without showing any disposition to heal. Probing the wound, I felt what, from its roughness, I thought was a piece of dead bone, but cutting down upon which I found to be a bullet. On its point and side were two deep indentations, to one of which a little bony substance was adherent. The patient then told me that he was shot before Atlanta, on the 21st of July, 1864, the bullet entering the abdomen, and that he had then remained in the hospital eleven months and finally been discharged. The wound had ever since remained open, discharging a little pus occasionally, frequently emitting flatus, and even soft, feculent matter, whenever he had a diarrhœa Upon inspection I found a small, fistulous opening in the left lumbar region, immediately over the upper portion of the descending colon, but I failed to pass a probe through it, though I have no doubt, from what he said, that it communicated with the bowel. The wound in the buttock healed rapidly, and the man, who was a railroad laborer, returned to his work. He gave his name as Andrew J. Bolstad, a Norwegian by birth, of Company K, 12th Wisconsin Infantry. As war relics are now getting scarce, I thought I would report this case.

John C. Sundberg, M.D.

Red Wing, Minn.

News and Miscellany.

Midwifery in the Sandwich Islands.

The *British Medical Journal* has a letter on this subject from Honolulu, describing the modus operandi of the Hawaiian midwife:—

"The midwives here are for the most part men—usually old men. When the woman's time draws near and labor commences, she is placed sitting on a man's knees, with her back to him. He then clinches his hands over her abdomen, and with all his strength hugs the woman to him, until the child is actually forced into the world, falling to the floor between the operator's feet. The umbilical cord is then cut, and always left very long. Then the woman is placed upon her feet, and the midwife takes her tongue, and draws it steadily until she gulps, or retches, this action causing the prompt ejectment of the afterbirth. After this she goes and flounders about in the sea, and returns to land, ready for such domestic duties as may fall to her lot or inclination. Native children are—as may be inferred from the way in which they are introduced to existence—very easily born; but should the baby stick at all, or make any bother about being born, then the mother knows it is going to be half white, as this latter kind of baby is so much bigger in the forehead. It is a wise child that knows its own father in this country. So well recognized is this fact that natives never ask, 'Who is your father?' but only, 'Who is your mother?' when they desire any acquaintance with one another's genealogy."

Bait for Ambitious Investigators.

The *Lancet* publishes the following list of prizes for 1883, offered by or through the French Academy of Medicine: The Prix de l'Académie is 1000 francs; the subject, to determine the Clinical Value of Antiseptic Methods in Surgical Practice. Prix Portal, 1000 francs, Is Tubercle of Parasitic Nature? Prix Civrieux, 2000 francs, Hysterical Paralyses and Contractures. Prix Capuron, 2000 francs, on the Influence of Sea

Bathing in the Scrofula of Children. Prix Godard, 2000 francs, for the best work on External Pathology (Surgical Disease). Prix Barbier, for the Discovery of a Cure for any Disease reputed to be Incurable, such as Epilepsy, Hydrophobia, Cancer, Cholera; part of it may be awarded for advancement in this direction. Prix Desportes, 1500 francs, for the best work on Medical Therapeutics. Prix Daudet, 1500 francs, Lymphadenoma. A prize of 2000 francs, under the name of the Prix de l'Hygiène de l'Enfance; subject, to determine by precise Observation the Rôle of First Dentition in Infantile Pathology. Prix Amussat, 2000 francs, for a work based upon Anatomy and Experiment leading to progress in Surgical Therapeutics. Prix Saint-Lager, 1500 francs, for the Discovery of a Cure for Goitre. Prix Saint Paul, 25,000 francs, for the Discovery of a Cure for Diphtheria; the interest of the capital may be awarded as an encouragement for work in this direction.

Frozen Food.

The *Medical Times and Gazette* says it is not generally known that some millions of the human race subsist for one-third of the year on frozen food, not only meat and fish, but also butter, game, milk, etc. We do not refer to the Esquimaux or Samoyedes, but to people living in the utmost affluence, who are compelled to resort to this kind of diet as often as winter comes round. That it is not unwholesome, appears from the fact that (excepting in St. Petersburg) the death-rate is no higher in the towns inhabited by people using this food, than in the average of towns in France; and that the meat loses none of its flavor after months of freezing, is admitted by all travelers. It will not be over the mark to say that twelve millions of people in the Northern Hemisphere consume one million tons of frozen food during the winter months. This does not include the frozen meat consumed in England.

The Detection of Sewer Gases.

The *Medical Times and Gazette* says that Mr. Macleod, the sanitary officer of Glasgow, has suggested a very simple and accurate drain test. The smoke of ignited cotton waste is blown by a machine into the whole drainage system of a building, and by issuing from the mischievous holes and crannies "discloses the position of a leakage with perfect accuracy." When no smoke appears it may be concluded, with perfect confidence that the pipage connected with the sewer is sound and safe. This defect detective is an improvement on the ether-vapor system which has been proposed for the same purpose.

A New Title for anti-Vivisectionists.

Professor Owen has suggested, in a little volume which he has just published, that his opponents, the enemies of vivisection, should adopt the title of "Bestiarians," and he confers on the Victoria-street Society the designation of "The Bestiarian Society." The word is not intended in any degree as a term of reprobation, but he suggests it as one desirous of helping the anti-vivisectionists in their aims, "so far as they do not harm the human species of animals."

Pasteur's Researches.

A sum of 50,000 francs has been placed at the disposal of M. Pasteur, by the French Minister of Agriculture, with the full approval of the Budget Committee. The money is designed to assist the researches M. Pasteur is conducting on the causes and nature of contagious diseases among animals, and is the third sum granted for this purpose. A similar amount was voted in 1880, and 40,000 francs in 1881. The French mind, it would appear, is capable of appreciating the importance of scientific work of this kind, and of encouraging its continuation.

Mortality of Black and White Troops.

The *Medical Times and Gazette* says: According to our Army Medical Department statistics, a striking difference is shown between the state of health of black and white troops. By these returns the black regiments appear to suffer vastly more than their white comrades, from the ill effects of tropical climates. Thus, on the West Indies command, while the mortality among white troops last year was slightly over 8½ per thousand, the deaths among the black troops were more than 19 per thousand.

Sir Erasmus Wilson's Munificent Gift to Margate.

At a recent meeting of the Governors of the Margate Royal Sea Bathing Infirmary, Sir Erasmus Wilson, F.R.S., handed over the key of the magnificent new wing of the Infirmary, to be named the Erasmus Wilson wing, which he has built at an estimated cost of over £150,000. The wing includes two large day-rooms and four dormitories, each to contain sixteen beds, with a swimming bath capable of containing 15,000 gallons of sea water.

Utilizing Orange-peel.

A gentleman in Manchester claims to have succeeded in applying orange-peel to a very useful purpose. Orange-peel dried in or on the oven, until all the moisture has been expelled, becomes readily inflammable, and serves admirably, either for lighting fires or for resuscitating them when they have nearly gone out. Thoroughly dried orange-peel will keep for a very long time, and might be collected while the fruit is in season, and stored for winter use.

The Common Mushroom.

The *Medical Times and Gazette* says that Professor Ponfick, of Breslau, has been making experiments on the common mushroom, and tells us in detail, and with the authority of science, what was somewhat vaguely known before, viz., that all common mushrooms are poisonous, but

cooking deprives them, in a greater or lesser degree, of their poisonous qualities. The repeated washing with cold water, which they usually undergo to clean them, takes away a portion of the poison, and boiling does the rest, but the water in which they have been boiled is highly poisonous, and should always be carefully got rid of. Dried mushrooms are still dangerous for from twelve to twenty days ; they require to be dried for at least a whole month, and are only really safe after four months' drying.

Items.

—The annual meeting of the New Jersey Sanitary Association will be held in Trenton, December, 1882.

—At the jubilee held at the Wurzburg University on the 3d inst., among the celebrities who received honorary degrees were Sir James Paget and Professor Huxley.

—In Providence, R. I., with a population of 104,000, not a single death has occurred from smallpox since 1875. The reason is given as "general and careful vaccination."

—On August 1st, a meeting was held in Queen Square, to promote a movement for the erection of an international hospital at Washington, in memory of the late President Garfield.

—Dr. William Pirrie, Professor of Surgery in Aberdeen University, has resigned. Drs. Alexander Ogston and Ogilvie Will are the two most prominently named for the succession.

—The Irish College of Physicians is about to make arrangements for granting certificates in Sanitary Science to licentiates of the College. The fee is fixed at five guineas, not returnable in case of rejection.

—M. Béchamp says that he has discovered living organisms in the gastric juice similar to the microzymes of the pancreas and liver. M. Gautier denies that these are living organisms, and states that they are merely protoplasmic granulations.

—Dr. L. P. Yandell says: "It was declared, a century ago, by John Hunter, that there are but three classes of skin diseases, one of which is cured by mercury and the iodides, the second by sulphur, and a third class which the devil himself can't cure." Knowing man was Hunter.

—It is the opinion of the most experienced health authorities in London that the poorer classes of Jews are naturally long lived, and that the dietary and other sanitary regulations prescribed by their religion enable them to battle for a considerable time against unhealthy surroundings.

—Unprecedented improvements have taken place in Vienna during the past twenty years. Nearly $40,000,000 have been spent on the city water works, school buildings, new town hall, main drainage, widening and paving of streets, and other useful and ornamental works, including the Danube embankment.

—A midwife in Prussia having washed the body of a person who had died of typhus, and carried the infection thence to a lying-in woman, the Prussian Government, under order of June 26th, 1882, has forbidden the laying out of corpses by midwives, under a penalty of 10s., or in default, three days' detention.

—The oldest university of Germany, Prague, has ceased to be a German university. The upper house in Vienna has passed the law, that from the first of October next the lectures must be given in the czechic language, and the examinations passed also be in the same tongue. This is, perhaps, the most foolish law ever passed by legislators. Who speaks or reads the czechic language? Besides Latin there are only three languages universally known—English, French and German. This decree will be the deathblow of Prague, of whom some said that it was getting ahead. After the loss of Klebs and Eppinger, whom have they left?

OBITUARY NOTICES.

SIR JAMES ALDERSON.

Sir James Alderson, M.D., D.C.L., F.R.S., Physician Extraordinary to the Queen of England, died recently in London, at a very advanced age. After taking the degree of M.D., in 1829, at Oxford, he settled in London, and soon acquired an extensive practice. He was President of the Royal College of Physicians from 1867 to 1870, inclusive. He was knighted Nov. 11, 1869, and Oxford gave him the honorary degree of D.C.L. in 1870. He was appointed Physician Extraordinary to the Queen in August, 1875. He was the author of "Practical Observations on Some of the Diseases of the Stomach and Alimentary Canal," 1847, and "The Lumleian Lectures for 1853-4."

DR. E. S. DREW.

Dr. E. S. Drew, a prominent physician of New Orleans, died recently in that city. He was a member of the Washington Artillery in the Confederate Army during the war, and was well known for the readiness with which he gave his services at all times to the poor and needy.

DR. GEORGE CAPRON.

Dr. George Capron, the oldest practicing physician in Providence, died Sept. 21, aged 81 years.

MARRIAGES.

VAN HARLINGEN—WHITNEY.—On August 31st, at All Saints' Church, Paddington, London, England, by the Rev. H. Bidwell, Bessie Butler, eldest daughter of John R. Whitney, of Bryn Mawr, and Dr. Arthur Van Harlingen, of Philadelphia.

WAGNER—VAUGHN.—On August 28th, 1882, at St. George's Church, Hanover-square, London, by the Rev. B. Savory, Clinton Wagner M.D., of New York, and Libbie Vaughn, daughter of the late Geo. W. Vaughn, Esq , of Portland, Oregon.

DEATHS.

BURPEE.—In this city, on the 14th inst., David Burpee, M.D , in his 56th year.

CLEMENTS.—On Thursday, September 14th, at Phœnicia, Ulster County, N. Y , Jas. W. G. Clements, M.D., of New York City, in the 67th year of his age.

SHANNON.—In Kingston, Ohio, August 24th, of lung and heart disease, Dr. R. W. Shannon, aged sixty-five years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

Lecture.

THE TREATMENT OF EPILEPSY.

BY M. MAGNAN,

Physician to the St. Anne Asylum, at Paris.

Gentlemen:—In order to complete the course of clinical lectures on epilepsy, it will be necessary to consider the treatment appropriate to the malady.

It would be very interesting to follow the therapeutic history of epilepsy, but in the treatise of M. Delasiauve you will find an enumeration of the diverse methods of treatment successively employed. As these lessons are meant to be essentially practical, we will confine ourselves to the consideration of those methods which appear to-day to give the best results.

Jaccoud very judiciously recommends careful research regarding the causes which led to the development of the malady, so as to obtain thus the principal indications for treatment. Unfortunately these causal indications are often wanting, or exceedingly obscure. I can, however, cite one case where the primary cause of the malady furnished excellent indications for treatment.

The epileptic attacks, sometimes complete, sometimes incomplete, came on in this case subsequent to the cicatrization of a wound on the heel from the kick of a horse; the attacks were preceded by an aura commencing at the wound. The painful cicatrix situated over the calcaneum was carefully and completely removed by M. Trelat. Since then the duration of the attacks has been much shortened, and they have not occurred so frequently, but have not completely disappeared. As the wound was received many years since, it is probable that section of the saphenous nerve would not have any favorable effect; in certain cases where chirurgical intervention has occurred soon after cicatrization, complete cure has been obtained.

Indications for treatment can often be drawn from the general condition and habits of the patient.

Anæmia and scrofula, for instance, which are so often found associated with epilepsy, should be energetically combated by remedies appropriate to these morbid conditions; if masturbation is practiced, or the patient constantly commits alcoholic or venereal excesses, every effort should be made to eradicate these bad habits.

Unhappily, however, the causal indications are wanting in most cases, and when they are recognized, it often happens that rational treatment is of no benefit, epilepsy being of such long date that it has become emancipated from its primary cause. In such cases it will be necessary to have recourse to the treatment which, up to the present, has given the best results.

As a general rule the bromides give the best results, and among the bromides, the potash salt seems to be most effectual. This salt was first used for epilepsy, in England, towards 1853, by Laycock and Wilks.

These physicians recommended it particularly in a form of epilepsy which seemed to be due to menstrual derangement.

Almost simultaneously, MM. Bazin, Hardy and Brown-Sequard experimented with it, and

somewhat later M. Germain-Sée studied its action in a number of cases, and drew the attention of practitioners toward it, in a lecture delivered at the Beaujon hospital. Since then the physicians at Bicêtre and at the Salpetrière, Falret, Voison and Legrande du Saulle, who observed the malady on a grand scale, have rendered its use common.

Its efficacy in many cases is incontestable. "The bromide of potash, says Gubler, sometimes cures, often ameliorates, and hardly ever proves of injury, in this disease."

M. Germain Sée, in a clinical lecture at the Hotel-Dieu, in March, 1877, proclaimed the bromides as constituting the only efficacious treatment in epilepsy. He founded his assertion on fifteen years' experience, treating exclusively by this method 130 patients, 58 remaining more than three years under observation. For myself I have experimented with all the new medication lauded in the treatment of the convulsive neuroses, but I return always, in the end, to the bromic salts, which are, in reality, of great efficacy in epilepsy.

The bromides, and particularly the bromide of potash, still forms, then, the basis of treatment; but we must call special attention to the manner of administering them. They should always be administered in solution, experience having demonstrated that their ingestion in the solid state determines grave lesions of the digestive tube. The salt can be administered in almost any of the liquids in common use, in water, wine, milk or bouillon. I give it preferably in one of the aromatic or bitter infusions, with the addition of a small proportion of syrup of orange-peel; these substances slightly stimulate the stomach and aid in the absorption of the drug.

Bromide of potash should be given in doses of one and one half or two drachms daily, but in certain cases of exceptional gravity, either on account of excessive frequency of the attacks or the delirium which follows them, it is found necessary to largely increase the dose, and carry it as high as two and one-half, or even three drachms.

I order it always to be taken just before meals; it is thus better tolerated by the stomach, and the treatment can be longer continued without inconvenience. By administering the bromides methodically, the patient can be maintained constantly under the influence of the drug, each dose taken increasing the action of the preceding dose.

As Gubler recommends, it is better to suspend from time to time the use of the drug, "in order to avoid the production of cumulative effects produced, not by the doses successively taken, but by a pharmaco-dynamic action of increasing pressure or tension" (sic).

When the attacks have completely disappeared, it will, nevertheless, be necessary to keep the system for months, or even years, under the influence of the drug. This may be effected without the constant administration of the medicament, by giving it at sufficiently near intervals. This is the sole means of rendering the cure complete when it is possible, and of keeping the attacks within bounds when it is impossible to completely eradicate the disease.

The treatment must be continued for several years; but as soon as the attacks have become less frequent and less violent it will be well to suspend treatment for five or six days and then recommence, and continue giving the drug for fifteen or twenty days, and again allow another period of repose. I have remarked that by pursuing this course, the diverse functions momentarily troubled by the action of the bromides become reëstablished more rapidly than if only one or two days of repose were allowed.

As you have observed in my hospital service, with the patients under constant surveillance, I am in the habit of giving much larger doses of the bromides than could be administered with safety in private practice, for under such conditions it is possible to speedily arrest any accidents due to bromism, if such supervene. The administration of large doses gives rapidly whatever good effects can be obtained from the medicament. Nevertheless, the dose should, as far as possible, be in proper proportion with the profession of the individual, and it should not be forgotten that those who lead a sedentary life have less tolerance for the medicament, and are most subject to the development of toxic symptoms.

I need not insist on the physiological and therapeutic action of the bromides. It must be remembered that some of these salts have an anaphrodisiac action, but less energetic in this respect than has been generally believed.

These salts give to the breath a peculiar characteristic odor, and produce later, if their use be long continued, anæsthesia of the pharynx, angina, an acnéiform eruption on the face and back, and sometimes on the lower limbs, veritable ecthymatous pustules, which leave deep ulcerations after them. In some cases, almost as soon as the medicament is given, derangement in the digestive organs

occurs (anorexia, epigastric pain), and intellectual dullness, with diminution of memory, general lassitude ; later on, muscular feebleness, with syncopal tendencies, and even vertigo, occur. When these complications supervene, the administration of the medicament must be immediately interrupted, and tonics given for the time being.

In cases where bromide of potash does not prove successful, or where it is not tolerated by the stomach, Charcot and Brown-Séquard have for many years recommended the employment of the other bromides, the bromides of sodium or of ammonium, either singly or associated together, in doses of from 1½ to 2 drachms. I have myself long experimented with the bromide of zinc, and in certain cases it proved successful.

M. Hublé, in a thesis written under the auspices and in the service of M. Bourneville, considering the constitutional conditions which should lead to the employment of one bromic salt in preference to others, gives the preference to bromide of arsenic, when the patient presents any marked predisposition to cutaneous disease.

Besides this, M. Charcot recommends cold douches during the period the medicament is administered, to augment the rapidity of absorption.

For the proof of this assertion, he refers to the experiment of Fleury, who remarked that the pupil became immediately dilated after the application of a belladonna suppository, when the cold douche was employed for a very short period, even a few seconds.

In some cases, no matter what may be the mode of administration, the bromides have no beneficial effect ; it will then be necessary to fall back on other methods of treatment.

If the attacks are very mild, coming under the category of those cases to which the term "petit mal" has been applied, or if they consist simply in unconsciousness, lasting but a few seconds, Gubler recommends the extract of belladonna, already employed by Trousseau in similar cases, in doses of one-half to one grain per diem, or sulphate of atropia, in doses of one-fiftieth to one-tenth of a grain per diem.

You are aware, on the other hand, that Herpin has recommended very highly the zinc salts, which gave him good results in certain cases ; we have recourse to them at present in cases where the bromides prove inefficacious. I myself employ the oxide of zinc, in doses of from five grains to forty-five grains per diem ; the valerianate of zinc, in doses of two to fifteen grains ; the lactate, from two to thirty grains, associated either with extract of valerian or conserve of roses.

Herpin also recommended the copper salts, but M. Bourneville, who has experimented with them methodically, has never observed any satisfactory results from their administration.

Finally, there is no need to add that these diverse forms of medication may be combined in several ways. One will often be surprised to observe cases which have not been benefited by any one of these medicaments taken singly, much ameliorated when two or more are simultaneously given.

The use of the bromides is followed, in the majority of cases, by a favorable result, even from the debut of treatment. But, after five or six months, it will be often found, to the surprise of the observer, that notwithstanding the continued use of the medicament, the attacks become again as frequent as before the commencement of treatment. It is at this time that a course of bathing and hydrotherapeutic applications will restore to the bromic salt its original efficacy, not only maintaining the amelioration obtained from it, but also rendering it more complete.

It is often necessary to administer tonics in connection with these medicaments, such as the soft extract of quinquina (Fr. cod.), the tincture of bark and cod-liver oil etc. The patients should use only aliments easy of digestion, and the evening meal should be light. This last recommendation is particularly applicable to patients who generally have their attacks at night.

Finally these patients, subject at any moment to lose consciousness, and always under the imminence of an attack, should receive special attention from those about them. They should be cautioned against mounting on chairs or ladders, against remaining too near collections of water or too near the fire ; in a word, they should avoid all positions or occupations where a sudden loss of consciousness might prove dangerous. Very many accidents might be avoided by proper attention to such advice.

—A solicitor in England has obtained a verdict against a town for $10,000, as compensation for personal injuries caused by drinking impure water supplied by the Corporation. The water in its passage through the service pipes had become so impregnated as to produce in the plaintiff's case every symptom of acute lead-poisoning. A point as to the liability of the Corporation was reserved.

Communications.

A CASE OF STRANGULATED HERNIA OF THE VERMIFORM APPENDIX—OPERATION—RECOVERY.

REPORTED BY E. H. BENNET, M.D.,
Of Lubec, Me.

Samuel Campbell, aged 64; occupation joiner and painter; constitution and general health has been good; resident of Eastport, Me.

About three years ago he found a lump in the right groin, which attracted very little attention. He thinks it disappeared at times; was never painful. About eighteen months ago he had several attacks of slight pain across the lower part of the abdomen, which he supposed to be colic or some trouble with his water.

On February 9th, 1881, about noon, he was seized with violent pain in the hypogastric region. He supposed this to be similar to the previous attacks, differing only in severity. Had no suspicion that there was any connection between the pain and the swelling in the groin. He continued to suffer for about two hours, when he sent for his family physician, Dr. L. P. Babb.

When search was made for the cause of the pain, a lump the size of a hen's egg was found in the right crural region. It was not painful nor tender to the touch, and felt like an enlarged gland. Supposing it might be a case of rupture, attempts were made to reduce it, with negative results. Morphiæ sulphatis, gr. j, atropiæ sulphatis, gr. $\frac{1}{50}$, was given hypodermically and followed by relief. The patient remained comfortable until the next morning, when the opiate was repeated, with a similar effect. Large enemas had been used, but failed to produce any action of the bowels. Physic was now ordered, but only followed by a return of the pain, when vomiting supervened.

During the evening of the 10th patient got easier and the tumor now had a softer feel, but up to this time it had presented all the characteristics of an enlarged gland.

Dr. H. B. Knowles, of Calais, being telegraphed for during the day, arrived at 11 o'clock, P. M. After examining the case he considered the diagnosis uncertain. The patient being free from pain and not vomiting, it was thought best to wait and in the meantime endeavor to act on the bowels by mild cathartics. Dr. Knowles also endeavored to reduce the enlargement, but without avail. The laxatives given acted as before, *i. e.* by causing a return of the pain and vomiting. During the day (11th) the vomiting became stercoraceous, when it was decided to operate and give the patient the benefit of the doubt.

The reason why surgical interference had not been resorted to sooner was, because the attending surgeons found it difficult to convince themselves that the tumor really contained either strangulated intestine or omentum. The feel of the tumor was everything but convincing, and it was quite rational to suppose that some internal obstruction was the true cause of the serious symptoms which presented themselves. When is was decided to operate Dr. Wood and the writer were called to assist, it being done at 2 P. M. on the 12th. During the morning the patient had vomited a large quantity of matter which had a decidedly fecal odor, and evidently contained fecal matter. No nourishment had been retained for some time; was considerable exhaustion, a haggard countenance, feeble pulse and cool extremities. As far as possible, antiseptic precautions were observed. When the strangulated portion was reached it was found to be gangrenous, and neither intestine nor omentum, but the free end of the appendix vermiformis.

The stricture was readily relieved; when, if permitted, the whole would have readily passed back into the abdominal cavity. The appendix occupied the femoral canal. Gimbernat's ligament could be felt to the inside; the femoral vessels to the outside, and Poupart's ligament in front.

The blackened tissues extended back about two inches and a half, behind which they were apparently healthy. A silk, carbolized ligature was tied around the appendix, above the diseased tissues, and the gangrenous portion removed.

The ligature was allowed to protrude through the wound, which was closed by interrupted sutures.

After recovering from the anæsthetic, the patient vomited a large quantity of extremely offensive matter; this proved to be the last of the vomiting.

Nothing worthy of special note happened during the after-treatment. An occasional enema kept the bowels in good condition. Tonics and stimulants were used throughout.

At the end of four weeks the wound had healed.

After the third month the patient resumed his work as painter (in-doors), and during the following summer worked on the outside of buildings, standing for hours on a ladder, and show-

ing his usual vigor. At the time of this writing he is enjoying good health; no return of the old trouble.

CENTRAL AMERICAN MEDICAL CURIOSITIES.

Collected for the MEDICAL AND SURGICAL REPORTER

BY FRED. C. VALENTINE, M.D.

I propose to offer the readers of the MEDICAL AND SURGICAL REPORTER a collection of curiosities, I may call them, as collected among the more intelligent people, and even frequently employed by physicians in the treatment of diseases. In justice to my Central American colleagues, I must premise that the best educated among them employ some of the ridiculous means I shall detail, only to yield to popular prejudice, and it is remarkable how a physician can raise himself in popular esteem by a case which improves, partly as a result, or perhaps better, notwithstanding, the ridiculous medication which the ignorant friends of the patient prescribe, and to the employment of which the medical attendant consents.

But apart from their consideration as mere curiosities, the reader will find some ethnological facts which seem to show that a number of recent discoveries in civilized materia medica are of very ancient employment in Central America. In the following recital I shall, of course, omit all discussion and criticism, except in instances where they are particularly requisite to show the line of thought which gives an alleged indication for a certain medicament or line of treatment.

Inasmuch as a sort of empiricism seems to guide the whole matter, no system is claimed, no do I make any attempt at classification, but shall simply recount whatever my notes and memory furnish.

Thus bees are used: Eighty to a hundred live bees are thrown into a pint of hot water, and half an hour later the liquid is strained through a cloth and administered in teaspoonful doses every two or three hours, to promote diuresis. It is claimed that this infusion will cure retention of urine as well, suggesting in both instances the use of apis melifica by the Hahnemannian followers.

Externally, bees are also used, by toasting and powdering them. The powder is mixed with an equal quantity of lard, and smeared on bald heads, to arrest and cure alopecia.

Bran is frequently packed into and upon slight wounds, to arrest hemorrhage. For cosmetic purposes a paste is made of it and allowed to ferment. When a sufficient degree of nastiness in flavor has been acquired to make an editorial paste-pot a desirable substitute, it is smeared upon the dark one's face (for in a majority of instances the fair one requires no such aid) under the presumption that it will soften the skin and blanch it.

A weak infusion of bran is largely employed in catarrhal affections of the respiratory and digestive mucous membranes.

Annotta is used as a tonic and an anti-dysenteric. The reddish paste is smeared on the skin as a prophylactic against the bites of mosquitoes and gnats.

Water has a limited application in disease. Sulphurous waters are used in chronic rheumatism and in skin diseases, and inveterate metrorrhagias are treated with three glasses of this water daily.

In epistaxis, cloths dipped in cold water are applied to the forehead and scrotum, and in post-partum hemorrhages to the loins, sacrum and abdomen.

A jet of water persistently thrown upon the head is recommended for that vague affection called *gota serena*, which may mean leucoma, pannus, and all forms of cataract.

Baths have their special indications; cold ones are recommended to young persons, warm baths to women, and hot baths to old people and those called melancholics.

Very cold baths of long continuation, are recommended twice a day for insanity, especially monomania.

Cold baths are prescribed for insomnia, involuntary emissions of semen, benign blennorrhœas and incontinence of urine.

The baths are limited, except in insanity, as follows: Cold baths should not exceed six minutes, and the hot bath should not be prolonged over seven, while the warm bath should not be enjoyed for over an hour. The last has many advantages claimed for it in inflammatory affections of the eyes, and of the abdominal viscera, in jaundice, in nervous affections and to facilitate childbirth.

Vapor baths are strongly recommended as a prophylactic and a positive remedy against rabies canina, which affection I have often heard spoken of, but never have witnessed in Central America. The dogs which I have seen killed for this affection were ill with ordinary convulsions. One of my patients, who was bitten by a presumed mad dog three years ago, is alive and well to-day, and I prevailed upon her not to have the dog killed. He died nineteen days

later, of convulsions. (I do not make this statement from any desire to appear humorous.)

With my friend Dr. L. L. Dorr, of San Francisco, who wrote on the question of rabies in the New York *Medical Journal*, I do not believe that real rabies has ever been observed on the Pacific coast.

Sea water as a beverage is recommended as a purge, when nothing more unsavory is at hand, and is said to be efficacious in chronic hepatitis, in jaundice and adenitis.

Sea baths are prescribed in rachitis and scrofulous affections, in chlorosis, chronic cystitis, sterility, in amenorrhœa and dysmenorrhœa, in cephalalgia, in chorea, and some forms of rheumatism.

Bathing in rivers which run from east to west is deprecated, and all baths are to be used but sparingly, or not at all, by convalescents, those predisposed to intermittents, and those suffering from pulmonary affections.

The alligator pear (Laurus persea, Spanish aguacate or agualate, in Peru, palta), which makes a most delicious salad, and by some is called vegetable butter, is accused by our Central American unprofessional colleagues, as being an innocent aphrodisiac, for those who enjoy good digestion.

The leaves of this plant are pulverized after being dried in the sun, and used in the following combination in dysmenorrhœa and sterility: Powdered aguacate leaves, fine iron filings, saffron and aloes, forty-eight grains each. These are well triturated together and mucilage of gum arabic is added. The resultant mass is divided into forty-eight pills, of which six or eight are taken per diem.

Aguardiente, distilled sugar-cane juice, is considered a carminative and stimulant to digestion. In extreme debility, from any cause, in cholera morbus and poisoning by arsenic, it is used. It is added to the many herb infusions which are prescribed as sudorifics.

Splenitis is treated by two tablespoonfuls of aguardiente with a pinch of salt, before the first morning meal; sufferers from drunkard's liver, however, add nothing to their aguardiente, and take it without reference to time or quantity, or any other consideration except a financial one.

A would-be authority on medicine says, in all earnestness: (I translate literally), "According to Mr. Richard, an injection (*we suppose into the urethra*, because the author does not say where) of half a tablespoonful of aguardiente efficaciously cures swelling of the scrotum, called hydrocele." I am glad to say that this treatment has never been employed to my knowledge, and I feel confident that I am not alone in my sympathy with patients who may have been induced to inject this spirit, by all who know that it rarely is under 40 proof. Old women, whose villainy is in proportion to their ugliness, insist upon curing all affections of the eyes in children by instilling aguardiente between the lids, upon the conjunctiva. A wretch ruined a case of scrofulous iritis for me in this manner, and the poor child, for all its life, will have to regret its great aunt's brutality, by wearing an artificial eye.

"Adlocucion," which I have not been able to find in any dictionary or other work at my command, is a treatment consisting in having a man in health pass the palm of his hand several times over a diseased part, at half an inch distance, blowing upon it between each "pass." This is considered very efficacious in erysipelas.

Garlic, mixed with flour, is used as a sinapism, and mashed alone, as a vesicatory. One or two cloves of garlic are skinned, and swallowed whole, to cure hiccough.

For mental derangements, garlic is boiled upon hot ashes or embers, and mixed with cow's tallow, one part of the former to two of the latter; this ointment is spread upon cloths cut the shape of insoles of shoes, and is sprinkled with a powder made of the outer shell of a native black pepper. The plasters thus prepared are applied to the patient's soles. I doubt whether physicians anywhere would recommend this treatment, even for malingerers.

The natives claim that if garlic is rubbed upon a loadstone it will lose its magnetic power.

Basil (ocymum basilicum) is used as a diuretic, emmenagogue and carminative. A quarter to half an ounce of the leaves are steeped in two pounds of boiling water, and taken ad libitum.

The tomentose wool of the cotton seeds, carded, is placed thickly upon recent burns, and the seeds are ground up with sugar, to make an orgeat, which certainly is a pleasant expectorant.

It is due to the Central Americans that I say that during the more than five years that I lived and traveled in their country I have never known the cotton root used to produce abortion, nor, in fact, any other drug. I regret to state that the only cases of fœticide have been among foreigners; of what nationality I will not reveal.

Lavender (Lavandula Spica L.) is considered valuable in paralysis, epilepsy and rheumatism, in half drachm doses of the powder. Indolent glandular tumors are treated with an ointment, made of one part of the powder to two of suet, which is spread upon a cloth, heavily sprinkled

with the powder, and then applied to the swelling.

A strong infusion of the bark of the almond tree is recommended in all kinds of intestinal worms.

Starch is used as a drink and injection in dysentery and diarrhœa. "Centipede's walk," *i. e.* the site of the introduction of the poison-claw of this insect into the skin, is treated by the application of a thin paste of starch and vinegar.

Starch is presumed to increase the action of tartar emetic, and is given as follows: Tartar emetic, one grain; starch, one-half scruple (12 grains Spanish Pharmacopœia), and sugar, one drachm (72 grains Sp. Ph.), well triturated and divided into 4 powders, of which one is given every fifteen minutes, in any drink.

Spider-web has been used, from time immemorial, as an antiperiodic, but is especially recommended in the quartan form. That of the small black spider, which builds its web funnel-shaped, within the holes in walls, is preferred. It is also claimed that it will cure the nervous symptoms in pernicious fevers. It is rolled into pills without an adjuvant and given from 20 to 25 grains daily.

Rice boiled in water or milk is used as a poultice on local inflammations. Rice water is claimed to whiten the skin. Continued use of rice as an article of diet is presumed to cause ocular inflammation, and (homœopathically?) is recommended in hordeoli.

The artemisia vulgaris has a reputation as a stimulater and promoter of menstruation, as a vermicide and as a remedy for epilepsy. A handful of the leaves are fastened to the loins by those who make long journeys afoot, to prevent exhaustion. Of course, artemisia is used, as is nearly every other remedy in this list, for rheumatism.

Sulphur is used as a purge, in "scrofula," in asthma, in affections of the bladder, in diseases of the skin, etc., etc. It is said to be particularly efficacious for spasms of the muscles of the legs, and for these is worn in little bags, tied to the inguinal region.

The egg-plant, boiled and mashed, is applied as a poultice, hot, to inflamed hemorrhoids.

The intestines of recently killed animals are wrapped around paralyzed parts, and I have seen patients placed as far as possible within the thorax and abdomen of an ox which was in the throes of death.

Crabs, rabbits and hares, which "ever have their eyes open," must rest sometime, perhaps after death;" but when made into soups are said to kindly communicate their much needed sleep to the partaker. Consequently they are prescribed in insomnia. Crab soup is also recommended in leprosy and phthisis.

Cordoncillo, a creeper which I do not know whether it has been classified or not, is prescribed for elephantiasis. Those who recommend poultices of the bruised leaves for this disease, claim that elephantiasis is a result of frequent attacks of erysipelas. This pathological view may have deterred me from investigating the matter more closely.

Those persons who are classified as "of sterling worth," because one cannot say anything else favorable of them, and "melancholics," are advised not to use cocoa in any form, as it is believed to be harmful to them under any circumstances. Others may take it boiled in milk or water, at all times, as it is very nutritious. It prolongs life more than any other aliment, and gives even to the skins of old people a certain freshness and a "lustful appearance."

Cocoa butter is nutritious and "sweetening" (antacid?) Pyroses which *are caused by ulcerations* are cured by a drachm of cocoa butter, taken three times a day, in hot water. This information was given me by a most intelligent person—not an M.D.

Coffee enjoys a reputation of possessing antiperiodic properties. For this purpose the following potion is prepared: Three-quarters of an ounce of the powdered toasted beans are boiled in four ounces of water, until reduced one-half. The aqueous tincture is strained and two ounces of lime juice is added to it. This draught is taken in the morning, two hours before the first meal.

Lime.—Lime-water is prepared by slaking one ounce in a pound of water, and shaking well. The water is poured from the sediment and a second water added. The supernatant liquor is "remedial." It is recommended as a positive cure in diabetes, which disease is recognized by the fact that bees, flies and other insects seek the urine. In these cases, four to six tablespoonfuls are given daily. In diarrhœas it is mixed with infusion of rhubarb root. "When children are dying of debility it returns them to life." In sciatica, lime, in powder, one part, is mixed with two parts of honey and applied along the painful region.

Sugar-cane root is recommended as a diuretic and sudorific. One ounce of the root is boiled in four pounds of water until reduced one-half, and all is taken during the day; in addition to which the patient drinks a large quantity of

water, about eight ounces every hour, and if he does not urinate and perspire freely, it is "because something serious ails him."

Barley water, with sugar and lime juice, is extensively used in catarrhs of all the mucous membranes. In coughs, equal parts of barley, marshmallow root, and elder bark are boiled together and strained. While hot, sugar and the yolk of an egg are added, and the dose is taken upon retiring.

"Raw onions, eaten, render the breath unsavory, irritate the stomach, and excite immodest desires. Therefore, they are not used by persons of a good education."

Indolent tumors are treated by poultices composed as follows: Onions roasted upon hot ashes, ground mustard and common soap, equal parts, are mixed with a sufficiency of water, and the mass is boiled until of cataplasm consistency.

(*To be Continued.*)

Hospital Reports.

PHILADELPHIA HOSPITAL.

A CLINICAL CONFERENCE.

BY JOHN M. KEATING, M.D.

Reported by W. A. Edwards, M.D., Assistant Pathologist to the Hospital.

The Syphilitic Diathesis.

Gentlemen:—I have several cases to show you this afternoon, which illustrate well a subject most interesting and important.

Let us study these cases separately:—

This woman, aged 25, a splendid specimen of health and youth, carries in her arms her baby, aged six months, which, as you see, unfortunately, bears the marks of an inherited diathesis.

The woman tells us that her first child, a boy, died when four months of age; it was born with snuffles, which persisted until death, the infant dying of cholera morbus.

This baby that she carries to-day, Mary M., was born with *snuffles*, and, as you perceive, still has them. You will also notice that it has an occasional dry, hacking cough; in an adult we would interpret this as syphilitic laryngitis. The child was vaccinated when four months of age, with bovine virus; a month afterward it suffered from a violent attack of varicella, the pustules leaving, as you see, marked pits all over the child's body, especially over the spine. Ten weeks ago this small tumor, about the size of a silver twenty-five cent piece, appeared on the right labia. You notice that it is painless, although at first it was attended by slight tenderness; in its earlier stages it was freely movable, now it has become attached to the surrounding tissues. It has a peculiar tint and shows no tendency to pointing, as an abscess of this size would. Upon palpation it gives to the finger a sensation of firmness, and also retains its shape under pressure, the purplish tint, however, disappearing. It possesses neither the elasticity of a fatty tumor nor the firmness of a scirrhus. We also observe, surrounding it, a tubercular infiltration, round, or perhaps oval, slightly elevated, of a deep copperyred color, and around it is a well-marked hyperæmic areola. All these points, taken in connection with the snuffles and cough, give us a clear history of congenital syphilis; the small tumor is the gummous syphilide or gummous tumor.

We notice a large gumma over the left trochanter, which exudes a thin, ichorous pus; here the lesion has gone on to ulceration, and presents the gummous ulcer; these ulcers, when they first form, are deep and sharply cut, they extend in all directions, until they form this typical ulcer, with its rounded outline and punched-out appearance; the floor is uneven and bathed with sanious, fetid pus; its edges are thickened and surrounded by an areola of hyperæmia. To the left of the occipital protuberance another characteristic tumor is seen. On the back, about the twelfth rib, you may notice two typical growths; one of them has opened spontaneously, like a furuncle, by a single aperture.

You note that this child is remarkably well nourished; it has never had a day's illness since birth; in fact, until varicella brought with it some change, or, at least, modifications of the typical eruptions, which were suspicious, there was no spot or blemish which betokened an inheritance of this kind. The mother volunteers that the child was born with a cold; but that this passed off without treatment. She also says that her other child was "born with a cold." Was this syphilitic coryza? I would call your special attention to the fact that the conditions present in the case are simply as you see it; there is no malnutrition; no lesions of the viscera, as far as we can tell, no diarrhœa, and no evidence of bone involvement.

We think that this very late appearance of the syphilitic diathesis is due, in all probability, to the inheritance of a very small dose, and my friend, Dr. Arthur Van Harlingen, who has studied the case with me, and to whom I am indebted for the grounds upon which I base the positiveness of my diagnosis, assures me that this patient affords a marked example, both in the character of the lesions and want of nutritive disturbances, of late manifestations, owing to mild infections. But let us turn to this other child, and study the contrast.

This little patient, baby D., aged fifteen months, was born in the house, but was taken out when about two months of age.

The resident accoucheur tells me that the child was born with a purulent ophthalmia and snuffles. We know nothing more of the infant until it was returned to us a few days ago, in its present condition, which, as you can see, is horrible in the extreme.

The little mite presents three well-marked condylomata around the anus; that is to say, just where the mucous joins the cutaneous surface, which, as you know, is a favorite seat for these manifestations. Around the mouth you see those fissures and cracks that are such a frequent accompaniment of this diathesis in infants.

Just over the left ear we notice three large, purulent blebs; each one is nearly as large as your finger nail.

The picture which this infant presents is horrible in all its details. You notice the emaciation, the skin merely covering the bones. The staring eyes, looking like an animated skeleton, the turgid veins, with all their tortuosities apparent, lying directly upon the skeleton, and covered only by the thin layer of skin, from which all the subcutaneous fat has disappeared. The abdomen is finely reticulated with a venous network, which gives the child a mottled-purple hue, but upon close examination you feel the skin parched and leathery, with brown, or rather, bronzed splotches of pigmentation. This peculiarity is noticed also upon the face, on the head, and in the folds of the groin. It alone is characteristic of this affection. Let us examine the mouth. You find the mucous membrane parched, with no secretions; the tongue is coated with a dirty fur, and patches, curd-like, are adherent to the whole mucous surface. These fungi, that you will find this to be, with your microscope, are pathognomonic only of low vitality or typhoid state. They thrive in conditions of low grade, and are *post hoc* and not *propter hoc*, in relation to the disease. You will note that the angles of the mouth have a few mucous papillæ; they are to be taken into consideration as evidence for your diagnosis; but most important still, is the fissured condition of the angles of the mouth, a dry, scaly fissure, with a bronzed tint, a condition which remains permanent for a long time after the other symptoms have succumbed to treatment. Let us examine the child yet more closely. You will notice these patches about the anus; they are papular, with a grayish centre, beneath which is an excavated pit, with sharp, jagged edges. You notice also this growth, hemorrhoidal in appearance, which is a condyloma, a true sign of congenital syphilis.

Now, gentlemen, let me warn you, these cases are infecting; they may have been the result of inheritance or they may themselves have resulted from infection, from contact with the mother's parts. As far as we can tell, this child has no special organic lesion which is killing it; it is gradually wasting, drying up, as it were, from a blight which is radical in its activity, affecting the nutritive processes *primarily*; supplying diseased blood and elaborating diseased fluid to digest the assimilated food. Whatever it takes, passes off undigested. The circulation is weak, and it has a short, dry, hacking cough, which is probably caused by the accumulation of bronchial and laryngeal secretion, which its debility fails to permit it to expectorate.

Fortunately, most of the children so diseased die in spite of treatment, notwithstanding the philanthropic attempts of those ultra-charitable folks, who, ignorant of the stains of wickedness, cry out in favor of an attempt to vivify the diseased germ. Fortunately, a kind Providence so ordains it that these children all die; those whose syphilitic manifestations develop soon after birth; the mortality being in proportion to the rapidity with which these symptoms show themselves. When the infection is slight and the lesions are late in development, treatment is important and valuable.

Our little patient has just died, and if you will follow me to the post-mortem room, we can there witness the pathological changes which have taken place.

Post-mortem.—Examination three hours after death. Subject is much emaciated and unusually small for its age. Head is rather small and typically quadrangular. Adipose tissue in all parts of the body is much wasted. Skin is extremely thin. At the junction of the cartilages with the ribs we notice a thickened or nodular appearance, that reminds one of a rachitic subject.

Lungs. These organs are studded with nodes and cheesy masses; these are also deposited in the parenchyma of the lungs. These masses resemble tubercle in their appearance and arrangement, but they are undoubtedly syphilitic in their origin. Numerous gummata are seen on the parietal surface of the pleura; some of these are as large as grains of corn, causing this very rough or ragged feeling that you note.

The peritoneum is also covered with these syphilitic granulations; the liver shows them in the parenchyma and scattered over its capsule in great numbers. The spleen and its capsule have not escaped the invasion of the disease. The mesenteric and lymphatic glands are enlarged, infiltrated and hyperæmic. Pancreas is found to be indurated, as are also the thymus and thyroid glands. Heart normal, containing no clots, the pericardium covered with granulations. Kidneys and suprarenal capsules are normal.

Let me show you another example of syphilitic eruption in this babe. This child, Baby O., age five and a half months, was born in the house; you have seen it before, and you may remember its appearance when it was presented to us suffering from varicella.

Although the mother was treated for rupia before its birth, you will remember the child exhibited no symptoms of sufficient importance to attract attention, with the exception of snuffles, until it was vaccinated with bovine virus.

You will note, to-day, an eruption, looking like eczema, upon the angles of the mouth, extending over the chin, and spreading from that point to a position just opposite the larynx. Is this eczema? I may say that it is not; it is not at this point that eczema appears, as a rule, and when it does so it is usually moist, whereas this eruption is dry, with a scaly surface. That child sitting opposite, with rosy cheeks, has eczema. If you approach it you will see that the redness of the cheeks is due to an eruption which is dry and scaly. It is a bright scarlet eruption upon a child otherwise with every appearance of good health.

Baby O. has this eruption also upon the back of its head; it is, at a distance, of a bronze hue; there are also pimples or boils upon the occiput, with loss of hair, or alopecia.

Syphilitic eruptions are frequently noticed upon the occiput; probably the heat and rubbing of the parts upon the pillow cause irritation. This baby is anything but a thriving child; its skin is dry and dirty looking, due to pigmentation; it has in the folds of the eyelid and in the groin patches of this peculiar eruption, and I am sure, from its general appearance, you will see enough

evidence at a glance to prove to you that it is not a simple eczema due to gastric disorder or strumous diathesis.

You will frequently have to make your diagnosis from what you observe in these cases, as a history of inheritance is most difficult to obtain. At times corroborative evidence will accumulate from the queries you have instituted after many visits, such as previous miscarriages, rheumatic pains, sore throat, or alopecia in the mother, or unsteadiness of habit in the father. You must be guarded in the expression of your views, but at the same time act energetically in your treatment, if you think you have sufficient evidence of your diagnosis, notwithstanding the most emphatic denials of the parents. We have seen her children, Baby D. and Baby O., break out with the primary manifestations when four months of age, after vaccination with *bovine* virus; a circumstance that might stagger a physician in private practice, after using what he knew to be uncontaminated humanized lymph.

Apart, then, from all history from its parents, you may recognize an infected baby, first, by the snuffles or "cold in the head" at birth. This is not a transitory coryza, but a protracted chronic ozæna, from the onset. If this child be extremely syphilitic, the other evidences may rapidly follow—roseola, the condylomata at the anus, the symmetrical, impetiginous or eczematous eruptions on the buttocks, perhaps with papules, some of which will undergo ulceration, with red, fiery edges covered with gray secretion, the whole having a copper-colored tint.

The child's nutrition is impaired, its skin is harsh, its circulation is poor. At times the finger nails show cracks at their matrices, or dactylitis may develop. The only bone lesion that you will usually note is the want of closure of the fontanelles, though at times cases will present themselves with joint lesions.

Pemphigus upon the palmar or plantar surfaces may be noted at birth or shortly after.

But in those cases which develop late, faulty inheritance may not show itself; the child may be, to all appearances, robust for some months after birth, as in Baby M.

The mucous membranes should always be carefully examined, for fissures at the mucocutaneous attachments, at the angles of the mouth, or mucous folds; these are pathognomonic.

As to the *treatment* in these cases, I generally place the mother on anti specific treatment, if the infant still receives her milk; in this way sufficient of the drugs will be absorbed to produce speedy amelioration of the symptoms. When the little patient has been weaned we order it small doses of iodide of potassium and mercury, in the meanwhile watching our patient carefully, in order that the first mentioned drug may not produce irritation of the gastro-intestinal tract; in a short time the system will tolerate these drugs, when we may cautiously increase the dose.

The local manifestations require the same treatment as similar lesions would receive in an adult.

The prognosis, as a rule, is good, where treatment is instituted early, and we can assure the parents of a favorable termination except in those unfortunate cases in which the inherited poison has been overwhelming in severity, as we saw in the case of Baby D.

Pulmonary Atelectasis.

Let us study the history of the post-mortem specimens before us.

At our last meeting we examined baby E., whose short history was given us by Dr. Charles W. Kollock, resident physician.

The age was supposed to be one or two months. It was a "foundling," picked up in the street, and consequently we judge that it has passed through all the trials incident to exposure, deficient nourishment, and bad treatment.

The history of its complaint was rather uncertain; there was nothing very definite about it to attract attention, except debility and a slight cough. The cough was accompanied by some rapid and inefficient breathing; fine mucous râles were heard throughout the lungs.

You may remember a feeble infant in this ward, an eight months' fœtus, in fact, prematurely born, as its mother was dying from phthisis, which we studied together a few weeks ago. This child presented all the symptoms and physical signs of pulmonary atelectasis. It died in a few days, and no post mortem was obtained. I call your attention to the similarity of these signs in these two cases. In the case before us, the right apex posteriorly showed dullness on percussion, extending to the lower portion of the scapula, and then separated from complete liver dullness, by a line of marked tympanitic resonance. At the apex, the dull note amounts to absolute flatness; and this was noticeable upon the other side, though not to so marked a degree. By placing the broad hand across the back, and noting the respiratory and vocal fremitus, we remarked the absence of a distinct vibration, which would be diagnostic of the consolidation from any form of pneumonia.

The auscultatory signs failed to show tubular breathing; a feeble respiratory sound was heard, gradually increasing, and accompanied by mucous râles, as we descended.

There was no fever; there was feeble, shallow respiration; there was, seemingly, no pain.

At the time of the examination I called your attention to the general feebleness of the child, its rapid and very weak pulse, and also the fact of the insufficient aeration, which, no doubt, failed to show itself by venous engorgement, as the child was a negro; still, the mucous membranes were darker than normal.

We have seen several cases of plastic pleurisy in infants, and verified our diagnosis in the post-mortem room. You noticed that it was a condition usually secondary, also that it occupied the pleura, especially that of the back, throughout its extent, and was not limited to the apices alone.

We found it occurring with measles and pneumonia, and in one case, with extensive tubercular disease, affecting not only the lungs, but also the serous membranes of the brain.

We then concluded that our little patient was

suffering from pulmonary collapse, and it was placed upon the following treatment: A hop poultice was ordered to envelop the whole chest, and quinia sulph., gr. ss, in suppository, twice daily. For the cough I ordered syrup of ipecac in liq. pot. citrat. Whisky, f℥ ss, in milk, was given in divided doses during the day. As the bowels were loose and the evacuations greenish in appearance, I ordered pulv. rhei, gr. ¼, sod. bicarb., gr. j.

Three days afterwards I was sent for, and found the little patient breathing very quickly, respirations shallow, face twitching, eyes alternately fixed and rolling. I noticed that the skin was excessively hot, the thermometer in the axilla registered 107⅘°. I immediately ordered the child to be placed in a bath of 100°, which reduced the temperature to 104⅖°; cold cloths were also applied to the head.

After this the child appeared to be somewhat relieved; at intervals the mouth and eyes would twitch slightly, no regular convulsion, however, taking place. The muscles of deglutition seemed to be paralyzed, as it could not swallow. It continued in this condition for two hours or more, when the temperature again began to rise, and the bath was repeated. Death occurred about an hour later.

The post-mortem revealed the following conditions: Brain was intensely congested, but no effusion was seen. Lungs: collapse, or atelectasis at the right apex and left base. No consolidation. The remainder of the lungs were strictly normal. Larynx and trachea slightly congested. Heart normal; a clot was seen in the right and left ventricles. The pericardium contained an effusion of a light straw-colored fluid, about one fluid ounce. Liver slightly fatty; spleen normal; kidneys normal; intestines normal.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, September 7th, 1882. Vice President J. Solis Cohen in the chair.

Case of Carcinoma Mammæ,

presented by Dr. C. B. Nancrede, for Dr. Chas. Wirgman.

Mrs. Josephine M., æt. 48 years, married at 23, the mother of three children, the last born sixteen years ago. Had nursed all her children, but the last died from marasmus, owing to the small amount of milk the mother had all through lactation. Lactation was free after the first two confinements. She never had had any abscess of breast, traumatism, or eczema of the nipples, although she had always experienced pain and uneasiness in the right breast when nursing. There was no trace of carcinoma in family history. A sister had had enchondroma of one of the metacarpal bones. When young the patient had suffered from dyspepsia, and on one occasion had had an attack of hæmoptysis. Of late years Mrs. M. has grown very stout, although never robust nor strong. About the middle of June, 1882, she first noticed a lump in her right breast, at its upper inner quadrant, about the size of a hen's egg. A few nights previously she had been awakened by a severe, lancinating pain in the right breast, but experienced no further inconvenience. She paid no attention to it. The mass did not seem to grow till handled; an exploring needle had been inserted, when the growth became softer, much larger, painful, and the skin and super-adjacent veins rapidly showed marked changes. I saw her, August 6th, 1882, with Drs. Wirgman and Hearn, when the only additional points to be noted were that the growth was freely movable, with the breast, upon the chest walls, and that a mass the size of a pigeon's egg could be felt in the axilla, under the outer margin of the pectoralis major muscle. Dr. Wirgman removed the whole breast, by two semicircular incisions, opened up the axilla, and removed all the glands up to the clavicle. This operation again emphasizes what Dr. S. W. Gross has specially insisted upon, viz., that although the axillary glands may appear, before operation, uninvolved, when the axilla is opened, numbers are often found enlarged. This accords with my own repeated experience. Although slow in healing, the case has done well since operation.

This case presents special points of interest, which I shall now dilate upon. In the first place, its history and appearance were eminently suggestive of a rapidly forming sarcoma, which was either cystic, or what at once suggested itself to me before etherization, one into whose substance hemorrhage had occurred. Upon careful examination under ether, the discovery of the enlarged gland at once suggested the strong improbability of sarcoma, which view I abandoned. After the removal, the microscopic appearances once more threw doubt on the diagnosis, as there was, for at least one-half, if not more, of the circumference of the growth, a distinct appearance of a capsule, and, as I had surmised, the tumor had been broken down by a hemorrhage into its substance. Subjected to microscopic examination, the specimen was again puzzling, since sections of the first piece, embedded, showed in every portion of their extent, with a very few slight exceptions, small spindle-cells, of a connective tissue type. Dissatisfied, I embedded a second piece, sections of which revealed a typical carcinoma, of the soft variety. This again illustrates what I have many times insisted upon in this Society, viz., that either very large sections of growths should be made, as Dr. Seiler advocates, or sections from several and varied portions of the morbid mass should always be carefully examined. Dr. Tyson said that the presence of a capsule seemed to be clearly demonstrated.

Recurring Carcinoma of Mamma and Axillary Glands.

Presented by Dr. C. B. Nancrede.

The patient, Mrs. F., æt. 37 years, from whom the specimens were removed, before the discovery of the primary tumor, about 18 months back was in perfect health, although, from pecuniary losses, she had undergone much mental anxiety since the Chicago fire. Hearing a vivid account from a friend, of another case of carcinoma mamma, her mind became deeply impressed, and shortly after she discovered a growth in the

upper inner quadrant of the left breast, which continued to grow until it had attained, at the time of the first operation, to the bulk of a small orange, viz: one year after her first discovering it. She lost much flesh from the time of the discovery of the growth; she had never suffered from any form of traumatism, had had no eczema of the nipple, and although she had borne one child a number of years back, and had suckled it, had never had sore nipples. There was nothing that could be fairly construed as a hereditary history of carcinoma. The primary operation had consisted in a removal of part of the breast. In less than two months after this a small nodule appeared in the cicatrix, while the axillary glands began to enlarge rapidly. On July 8th, 1882, I saw her, in consultation with Drs. R. R. Taylor and Harlow, when I found that there was a small nodule in the middle of the original cicatrix, while the axilla was occupied by the mass of indurated glands which I here present. The growth partially embraced the axillary artery, since, when the former was compressed, the radial pulse was decidedly affected. Not being allowed to remove the whole breast, I freely excised the small recurrent growth, and after a tedious dissection, removed the axillary tumor, laying bare the artery and vein for a space of over an inch, clearing everything out to the clavicle, and distinctly recognizing the coracoid process of the scapula. Although not the place for a clinical discussion, I cannot refrain from emphasizing the importance of the thoroughness with which this axillary dissection should be performed. Not a single gland should be left, enlarged or not. Properly conducted there is hardly any hemorrhage, a vessel rarely requiring ligature. This case was treated on the Listerian principles, but with a spray of acetate of alumina, and the wound was dressed with the same. There was no inflammation, heat, pain, nor subsequent induration, and if I remember rightly, the case required but five dressings, until the wound became superficial, and fewer would have been necessary had perfect coaptation been secured. One or two points where stitches made marked tension, showed a surrounding skin flush, which disappeared on the removal of the stitch; immediately contiguous to this the wound edge looked as if made but a few minutes before, thus showing that the irritation of tension was the trouble, which, as before said, very rapidly disappeared when the deeply imbedded stitch was cut. The temperature rose to 100.2° at the end of the first 24 hours, after which it remained under 100°. The pain after the removal of the pressure of the bottom stitches, amounted practically to nothing, according to the patient's own statements, and it will be remembered that she had the experience of a former operation for comparison. I believe that this is the first case where acetate of alumina has been used in this city, in a Listerian operation, and its success disposes of the absurd statement that carbolic acid is Listerism.

Carcinoma of Stomach.

Presented by Dr. J. H. Musser.

The clinical aspects of this case were so definite, that when this man applied at the medical dispensary of the Hospital of the University of Pennsylvania for treatment, early in April, of this year, it was without difficulty that malignant disease was diagnosed.

He was a farmer, of good habits, 53 years old, and previously in good health. For the last six months he had suffered from "weakness of the stomach" and general debility, which prevented him from working. He had lost much flesh, and had constantly a severe sickening pain in the epigastrium, extending to the upper part of the lumbar region, which became much worse within an hour after eating; appetite was poor, tongue clean and pale, bowels constipated, with troublesome flatulence. A tender, non-pulsatile, movable tumor, extended across the epigastrium, from the margin of the ribs on one side, to a similar site on the other, one inch and a half above the umbilicus. He presented an anæmic, cachectic appearance.

Dr. H. Plank, of Morgantown, took charge of the case, and wrote me, April 21, 1882, that he was much benefited by the treatment instituted, but was confined to bed, from sheer exhaustion. June 5, the doctor reported increased weakness, and emaciation, and that the pain had extended along the left side to the same shoulder. He took but little nourishment, and he commenced vomiting (June 10,) undigested food, mucous, grumous, purulent matter. He died June 20, of exhaustion, after a nine months' illness.

Dr. Plank kindly sent me the specimen I here present. One fourth of the pyloric end of the stomach is involved in the growth, which extends along the greater curvature for four inches, along the lesser two inches, and completely encircles the organ. The stomach walls in front of the disease were dilated, the muscular coat being hypertrophied, and the mucous membrane congested. The mass encroached upon the calibre of the viscus so as almost to occlude it. The tumor consisted of three nodules, one of which was ulcerated on its mucous surface, and presented the appearance of a scirrhus. The glands in the lesser omentum were diseased.

Spindle-celled Sarcoma of Thigh.

Presented by Dr. J. Henry C. Simes.

The patient from whom this specimen was removed presented himself for admission to the Episcopal Hospital on Aug. 30, '82. He is 60 years old, an Irishman, and gave the following history: Two years ago he first noticed, at the lower and outer part of the thigh, a small swelling, which grew rapidly to the size of a hen's egg, when it was removed. Shortly after the wound had healed a second tumor was noticed in the cicatrix, having the same character as the previously removed growth. This was also removed by operation, and again, in a still shorter interval, a third similar growth was developed in the same locality, which was also removed by the knife. When admitted to my wards there was found, upon examination, at the lower and outer part of the thigh, a linear cicatrix about two inches long, beneath and adherent to which, as well as to the

surrounding integument, was seen a tumor as large as a walnut, movable upon the deeper tissues, painless, dense, and irregularly nodular. There was no glandular enlargement observable. No other tumors were present. The tumor was readily removed, being adherent only to the overlying skin, which was included in the incisions. Microscopic examination showed that the neoplasm consisted entirely of large, spindle-shaped cells, which contained large, oval nuclei.

Editorial Department.

Pain at the Heart and Palpitation.

Dr. J. Burney Yeo publishes a very valuable lecture in the *Lancet*, on this subject. There are few symptoms that we are more frequently called upon to relieve than pain at the heart and palpitation, and in nine cases out of ten these spmptoms are referable to dyspeptic conditions or to hysterical states. Pain anywhere in the left side of the chest, and often pain in the epigastric region, are commonly spoken of by the sufferer as "pain at the heart." While this pain may have nothing whatever to do with the heart, yet I have been somewhat surprised, while carrying out the method of exploration about to be described, to find in how many of these cases, where "pain at the heart" has been complained of, there has been quite unmistakable tenderness on pressure with the tip of the finger over the seat of the apex beat. The following different causes of thoracic pain may be incorrectly referred to the heart: Intercostal rheumatism, intercostal neuralgia, costal periostitis, of syphilitic origin, pleuritis, pain and discomfort attending flatulent distention of stomach. Under this last head I would mention one of the effects of abuse of tea, coffee and tobacco. Either of these, but especially tea, will frequently give rise to a form of dyspepsia, associated with vague pains in the chest, not always limited to the region of the stomach, but often referred to a spot higher up on the left side of the chest, and commonly accompanied with disturbed cardiac action and a nervous apprehension of the existence of heart disease. Finally, there is a pain usually spoken of as "sub-mammary," which you will often hear complained of by young women who are anæmic, or who suffer from menstrual derangement. It is frequently associated with tenderness on pressure over the ovaries, especially the left one. These several varieties of pain can be recognized by looking for the well known characteristic signs of each.

Dr. Péter considers the following method of examination of equal importance with that of auscultation or percussion. You must bear in mind that the cardiac muscle in the healthy state is insensible. (The method I am speaking of consists in simply pressing with the tip of the index finger, and with moderate force, along the intercostal spaces corresponding with the præcordial and præ aortic regions, and generally on the several points in the thoracic and cervical regions which are in relation with the organs whose sensibility we wish to explore.) Patients who suffer from chronic myocarditis often complain of a dull, heavy, almost constant, deep-seated pain in the region of the heart, aggravated at times under the influence of emotion or any considerable effort, and shooting then into the back. In such cases pressure with the tip of the finger along the intercostal spaces in the præcordial region, close to the sternum and over the ventricle, will constantly afford distinct evidence of the existence of a morbid sensibility of the cardiac muscle. The patient will often complain of severe pain when pressure is made over certain definite spots. In these cases the pain is especially felt in the fourth and fifth left interspaces when the surface of the ventricle is in contact with the wall of the chest, and also over the cardiac apex. And pressure over the apex will remain painful even after the pain has disappeared, under suitable treatment, from the other points.

Dr. Péter has noticed that in middle-aged men who suffer from the excessive abuse of tobacco, pressure over a very limited point on the third left intercostal space, near the sternum, will give rise to acute pain; and he thinks this point corresponds with the auriculo-ventricular groove, and that this strictly localized pain is probably due to a morbid condition of the ganglion of Remak, consequent on tobacco impregnation.

Pressure over the præ-aortic region is also of special importance in exploring the sensibility of the cardiac plexus and its tributary nerves; but it is necessary to be careful not to press too strongly over this region, as an attack of angina has been induced by neglecting this precaution.

Dr. Péter mentions that pain in this situation is very significant of lesion of the aorta affecting the whole thickness of its walls. In such cases Dr. Péter has found, and I believe, been able in several cases to corroborate his statement to a certain extent, that there is tenderness on pressure over the pneumogastric, at the root of the neck, especially on the left side, and in other parts of its course.

Now, there is one clinical fact you may accept undoubtedly, and that is, that complaint of cardiac pain is much less common in mitral than in aortic disease.

Several illustrative cases were exhibited.

Successful Transfusion of Blood.

In the *British Medical Journal*, Dr. William Walter relates the following case:—

On June 8th, 1881, Mr. Saberton, of Ardwick, was sent for to attend a patient, aged twenty-two, in her second confinement. On reaching

the house, he discovered that the child had been born and the placenta expelled at least ten minutes previously, and that the labor had not extended over more than a couple of hours. The condition of the patient was most critical; she lay in a pool of blood, her face deadly pale, and the pulse scarcely to be felt. Her abdomen was distended with an enlarged uterus, that reached almost to the ensiform cartilage. Not a moment was lost in firmly grasping the fundus uteri, and in resorting to the ordinary means of checking hemorrhage, including the free administration of ergot; but no contraction ensued until the hand had been introduced into the interior of the uterus, and the clots which filled the uterus thoroughly removed; and these, when lifted into the chamber-utensil containing the placenta, completely filled that vessel. The uterine contraction was soon followed by dilatation, with a return of the hemorrhage; and for an hour contractions and dilatations followed one another at short intervals, with repeated recurrence of hemorrhage. During this time, pressure over the fundus was maintained, and occasionally the hand was reinserted into the cavity of the uterus and the organ manipulated bimanually.

In the course of another half hour, the hemorrhage ceased, and the uterus remained firmly contracted. Notwithstanding this, the patient showed no signs of coming out of her collapsed condition; and it was evident that, if it were possible to save her life, it could only be by transfusion of blood. For this purpose I was sent for, and reached the house two hours after the labor, and half an hour after the arrest of the hemorrhage.

I found the patient lying still and unconscious; her face and lips were blanched; her eyes had assumed that dull and lifeless appearance which only death, or its near approach, can produce. Respiration was scarcely perceivable, and the pulse could only at intervals be felt; her extremities were cold and clammy, but the uterus was firmly contracted. It is needless to say I had no hesitation in concurring with the opinion already expressed as to the necessity for transfusion, and placed in readiness Dr. Macdonnell's transfusion apparatus. The husband of the patient cheerfully consented to supply the necessary blood, but her mother begged that she might be the donor; and to this request we acceded, as the condition of her health was extremely good. The mother's age was forty-two; and it is worthy of record that her next menstrual period, which should have occurred two days later, did not on that occasion appear.

While Mr. Gwatkin and I were performing venesection on the mother in an adjoining room, and before we had time to collect more than four ounces of blood, Mr. Saberton acquainted us that the patient was apparently lifeless. Accordingly, Mr. Gwatkin took charge of the defibrination, and I hurried back to the patient's bedroom to prepare her arm for the reception of the blood. The difficulty one had to contend with in finding a vein was very great, but at last one came into view; and, the skin over it being divided by transfixion at right angles to the course of the vessel, a probe was readily passed underneath the vein, so as to isolate it from the surrounding tissues. A small opening was now made in its walls, and the silver nozzle of the tube was introduced a short distance into its interior. The blood was not allowed to flow along the tube until it appeared at the opening in the side of the nozzle, whereby one knew that no air existed in the tube. The nozzle was then introduced further into the vein until the opening in its side was completely hidden from view; and the patient's arm, together with the apparatus, were elevated, in the hope that the blood would then be forced along by gravitation; but such was not the case, and it was necessary to aid in its propulsion by repeatedly compressing the dilated portion of the tube.

In from ten to twelve minutes all the blood (nearly four ounces) was injected, and the patient's arm being bound up, we anxiously watched the results of the transfusion. Almost immediately, respiration became distinctly visible and audible, without the occurrence of any dyspnœa; the pulse at the same time returned to the wrist; and, in the course of a quarter of an hour, the insensibility gave way to consciousness, and she was able to recognize her friends. Her convalescence was steady and uncomplicated; and within a month she was able to walk out of doors.

In conclusion, I may remark how generally it happens that, in the cases of *post-partum* hemorrhage which would be most benefited by transfusion of blood, a transfusion apparatus is not procurable until too late to be of service to the patient; and I cannot too strongly recommend a glass pipette, with tube, should be constantly carried in the obstetric bag, for sudden emergencies.

Troublesome Labors.

Dr. W. Howard Cory reports the following cases in the *British Medical Journal*. They will carry comfort to others who may have similar trying experiences:—

Case 1.—On July 1st I was called in to attend a Mrs. P. in her first confinement. I found the patient reclining on the bed in great agony. The os uteri was fully dilated; and I was much puzzled at feeling, instead of a fœtal head, a large, soft, fluctuating mass. Being anxious about the case, I sent for my partner (Mr. Orfend of West Town), who, after making an examination, came to the conclusion that some portion of the child's back was presenting, and recommended turning. I therefore administered chloroform; and, after about one hour's manipulation, my partner succeeded in extracting, with some difficulty, a male child (dead), with a hydrocephalic head. In this case the presentation was natural; but the state of the head caused the deception. The mother in this case made a rapid recovery.

Case 2.—On July 30th I was sent for to attend a Mrs. B. in her second confinement (her first child having been born six years previously). The nature of the case necessitated the use of forceps; but it was only after using considerable force that I was enabled to bring the head of the child into the world, and I awaited the natural expulsive powers of the uterus to com-

plete the delivery. I was surprised, however, to find that, notwithstanding the sharp pains the woman continued to experience, the body of the child still remained firmly fixed. As several minutes had elapsed since the birth of the head, and believing that the child would be sacrificed, I placed my hands on each side of the head (I was quite unable to hook my fingers under the shoulders), and, after using some force, succeeded in completing the delivery. The child, when born scarcely showed any signs of life, but was quickly restored by a little shaking. The woman, with the exception of a lacerated perineum, is doing well. In this case the child was a very large one.

Case 3.—I was called a few days ago to visit Mrs. W., aged 26, a primipara. The midwife who attended had not been able to manage the case. On making a vaginal examination, I found the head resting on the perineum. Thinking to expedite delivery, I put on the forceps; but, to my surprise, found, on making traction, that the head appeared to slip from between the blades. which were withdrawn on several occasions without success. After some perseverance, however, I managed to get the blades fixed; and with some trouble delivered a child with a very elongated head, from before back, much flattened from side to side, and with a tendency to hydrocephalus. The mother and child are doing well. In this case the head of the child was particularly narrow across the parietal region, while it was much swollen over the frontal and occipital regions; and it was owing to the blades being placed over the former position that the head slipped away whenever I made traction.

Case 4.—Mrs. H., aged 32, was seen by me on August 13th. The patient had been confined twice previously, of still-born children. The labor, although very severe, was natural; but, as the woman was becoming worn out with pain, I applied the forceps, and extracted what appeared to be a dead child. Much to the amusement of the nurse (who appeared to think it absurd on my part to do so), I endeavored to restore animation in the child, by Sylvester's method. I was rewarded, in about half an hour, with complete success. At the present time, the mother and child appear to be doing well.

Sub-luxation of Fourth Cervical Vertebra—Recovery.

Mr. Barwell reports the following case in the *British Medical Journal*:—

M. C. C., aged 63, was brought to the hospital on June 6th, 1882, by policemen. It was stated that, in a fit of despondency, the man had fastened a rope to some firm object in his room, had tied the other end round his neck, and thrown himself from the window; the fall was eleven or twelve feet. He was seen to fall, and was immediately released.

Mr. Pittard, house surgeon to the hospital, found him quite unconscious, breathing with some difficulty, and very slowly. The limbs were perfectly flaccid: no sign of sensation, no reflex action, could be produced by pinching them. The only external wound was a broad but slight abrasion, extending from behind the angle of the jaw to the middle line, about the region of the cricoid cartilage. On examination behind, Mr. Pittard found evident displacement of parts. He at once sent for the surgeon, who shortly afterwards arrived.

Mr. Barwell found the man lying perfectly still, but the limbs were not entirely flaccid; they did not, at the time of his examination, when raised, fall quite inert on the bed. Also, when the man's hand was lifted, his elbow supported by the mattress, and he was told loudly in his ear to keep it so, there was an evident effort to obey, although it sank slowly down. The pupils were contracted, but moved slightly to light. The breathing was between 17 and 20 per minute, the pulse was 24. The state, therefore, had evidently improved in the three-quarters of an hour since his admission.

On tracing the line of the cervical vertebræ upward, the seventh, sixth, and fifth were in their normal place, but then there was a sudden gap. Indeed, the fifth could be felt unusually distinctly, the fourth and third not at all, the upper part of the cervical spine being in a line much more anterior than the lower part; while the parts covering it were very soft and yielded easily to pressure forward. Nevertheless, since the breathing was normal, or nearly so, and since the man's condition was improving, Mr. Barwell would not undertake any attempt at reducing the displacement, but ordered him to have only a very low pillow, to which the head was to be secured by bandages.

June 7th. The man passed a quiet night, but it was impossible to say whether he really slept, or remained simply semi-conscious. The temperature was 101.5° At this date, he complained of pain at the back of the neck, but not very much; he was greatly troubled by a pain round the lower ribs, what he called "an iron hoop round him."

June 8th. There was no material change: the sense of constriction at the lower part of the thorax continued, but was less severe. The upper part of the neck behind was less yielding.

June 9th. The cord-like feel was now slight; the neck seemed assuming a more normal position.

June 11th. There had been no further evidence of spinal injury.

June 13th. The cervical vertebræ had very nearly resumed their normal position, being no doubt, as Mr. Barwell explained, slowly reduced by the elasticity of the intervertebral fibro-cartilage.

June 16th. The man was virtually well, and the neck normal in shape. He was kept in the hospital a few days beyond the above date, as it was thought better not to risk the effect of his being brought before the magistrate; but he was quite well, and had sustained no permanent injury.

Surgical Accidents in the Insane.

Dr. N. Schüle, of the Institution for the Insane, of Illenary, gives a history of surgical accidents as they happened among the insane who came under his charge. The *Deutsche Medizinal*

Zeit. (August 3d, 1882) mentions a few of the more interesting cases as they are published in the *Allg. Zeitsch. f. Psych.*, xxxix, 1. Schüle reports only such cases where the insane inflicted purposely the injury on themselves, and omits all cases which ended fatally; he reports, therefore, cases of a quasi monomania for self-inflic tion of surgical injuries.

Depilation in consequence of automatic actions in anæsthetical idiots or induced by hallucinations. One patient tore out the hairs of his beard singly, in the supposition that he would become an angel and receive for each hair a feather.

Then cephalhæmatoms, in consequence of hitting the head. Not rarely, nails, broken pieces of glass, and needles were pushed under the scalp. One melancholic insane drove a nail through his temples. Others tore out the eyelashes, or rubbed sand into the conjunctivæ. In consequence of continuously rubbing his eyes with his arm sleeves, one insane was attacked by double-sided iritis, cataract, and at last, perfect blindness. Another pushed some long, sharp-pointed pieces of wood into his ear passages, till otitis interna, and at last deafness, set in. In one case an insane, while under hallucinations, cut his tongue off totally, at the root, with an extremely dull pocket-knife, the edge of which was broken all over. The enormous defect gradually healed by granulations, which pushed themselves so far forward that at last the speech became intelligible again.

Very rich is the chapter on swallowing of all kinds of substances. One patient tore a living toad into pieces with his teeth and swallowed it. Glass was swallowed often, and without any damage. The passages in one such case looked as if they were covered with trachyta.

One chronic maniac tore, during one night, several yards of a thick woolen carpet off, and swallowed the same *in continuo*. A coprostasis was the consequence, and with the aid of fingers and a long forceps the corpus delicti appeared, gradually unrolling itself, like a huge ribbon.

In another case the 2-3 ctm. thick and 15 ctm. long handle of a spoon was swallowed. Some months later some small pieces of the same, thickly covered with blood, made their appearance in the fecal discharges. The hemorrhage was great, and accompanied by severe colicky pains. About a year and a half later the rest of the handle was extracted from the bottom of a large abscess in the ileo-cæcal region. The wound healed without leaving a fistula. It must be remarked, that the gravest injuries of such character generally healed far more favorably than would have been the case in healthy persons, had they met with similar accidents.

The nipples of the breast were frequently tied off by female insanes. Very often injuries are inflicted on the genital organs and the anus.

One patient extirpated his testicle, having lost the other in a battle. Others again amputated the penis. One female idiot has pushed a comb so far and with such force into the vagina, that its teeth penetrated the rectum and the mucous membrane of the same. Most of the injuries were committed during the night, and mostly with instruments of which nobody would have had any idea that they ever could be made use of for such purposes.

A Rare Form of Senile Gangrene.

Dr. Joseph Bell thus writes, in the Edinburgh *Medical Journal*: W. H., aged 75, a very healthy, temperate, contented old man, of spare habit and fairly healthy arteries, was sent into hospital, under my care, by Dr. Bentley, of Kirkliston, on 17th January, 1882. The second toe of his right foot was black and evidently dead. He said that a few days before admission he had met with an accident, the iron plate of a retort having fallen on his foot. The whole foot was red and swollen; not much pain, and no constitutional disturbance. On 24th January the dead toe was nipped off with scissors, no blood being lost; the tendons alone required division. The bones were noticed to be curiously macerated, as if they had lain long in water. In another fortnight the third toe, which on admission had been alive and healthy, except for a slight redness, also died and was lifted off, the bones being macerated, and this time the tendons also destroyed. The resulting gap left by the removal of these two toes was large but painless, and suppurated freely, with little odor. Up to March 10th all went well, and the wound was nearly healed. The extremities of the second and third metatarsals had separated from their shafts at the epiphyseal junction, and were lifted out with ease.

On March 10th, however, without either pain or elevation of temperature, a dark blush was noticed all over the great toe, which had hitherto looked healthy, and half way up its metatarsal bone. The circulation in this area was exceedingly sluggish, the finger leaving a white dimple on pressure, which took several seconds to refill with blood. After two or three days of doubt a bulla was noticed to form just on the dorsum of the metatarso-phalangeal joint. This bulla rapidly raised the cuticle to the size of a florin, and, being cautiously cut into, showed the true skin, not, as is usual in such cases, either shriveled up or sloughing, but as if it had melted into a shreddy, pultaceous mass, and this involved not only skin, but cellular tissue, ligaments and periosteum, for by March 20th, without any displacement of parts, suppuration, or odor, the proximal phalanx and metatarsal head were both exposed, as if thoroughly macerated, and lay loose in this pultaceous mass. The edges of the ulcer or cavity were everted and undermined, as if by a gumma, were of a pinky redness, but exhibited no granulations or any attempt at repair. Having watched many cases of senile gangrene to death or recovery, and having had two or three cases of gangrene from embolism also, for months, under careful observation, I am quite familiar with the usual processes of separation, whether moist or dry; but I have never seen or read of any case in the least resembling this one, whether in its rapidity of maceration of tissue, its curious cessations or intermissions, its freedom from pain, and apparently trifling effect on the constitution.

The treatment was purely expectant, no interference that could be avoided, absolute rest in bed, milk diet, which was well borne, and locally

keeping the limb at an equable temperature by cotton wadding (carbolized) and marine lint, to sop up discharges.

The result has been remarkable. To-day, 30th June, the apparently dead and macerating heads of metatarsal and first phalanx have recovered themselves, granulations have formed, and now the wound has closed, with the exception of a line of granulations about a quarter of an inch long and one-sixth of an inch broad, under which can be felt a thin scale of carious bone. The old man is quite well, and goes home in a few days.

Syphilitic Re-infection of Husband and Wife.

The London *Medical Record* says that Dr. C. Pellizzari, of Florence, reports the following case (*Lo Sperimentale*, March, 1882). About the middle of December, 1880, a healthy-looking married man, about fifty years of age, consulted Dr. Pellizzari for phimosis, with discharge from beneath the prepuce, and enlarged inguinal glands, which had followed a suspicious intercourse some days before. Induration of the corona subsequently became well-marked, and in due course a macular syphilide appeared, having been preceded by osteocopic pains. The man, on being told that he was suffering from syphilis, remarked that he had suffered from venereal sores ten years before, and had also at that time infected his wife, who, a few months afterwards, during pregnancy, had suffered from general debility, headache, and moist papules of the genital organs. Her child also showed signs of syphilis soon after its birth. Further and positive evi dence of the wife's infection was obtained from Professor P. Pellizzari, who had attended her in 1873, for syphilitic perforation of the septum nasi. On February 2d, 1881, she was examined by the author, and found to have an indurated sore of the fourchette and enlarged inguinal glands ; a month later a maculo-papular syphilide appeared. The two attacks of syphilis in the case of the wife are thus clearly proved ; but as regards the husband, the evidence of the former attack appears to rest on the fact stated by the man himself, that he had ten years previously contracted venereal sores after suspicious intercourse, and on the proof of subsequent syphilis in the wife and child. The husband appears to have suffered so slightly on that occasion, that he did not think it necessary to obtain medical advice. In connection with this it may be mentioned that, in the later attack, when he was under the author's observation, the general symptoms were mild in degree ; while the wife suffered severely from recurrent eruptions, nodes, etc., although she had been almost continuously under treatment during the preceding ten years.

An Attempt at the Operative Treatment of Ozæna Fœtida Simplex.

The Edinburgh *Medical Journal*, quoting from R. Volkmann, in *Centralb. für Chir.*, says :

During the past year I have attempted, in two cases of ozæna fœtida simplex affecting young girls, to procure a better ventilation of the nasal cavity by removing the whole of the inferior and the greater part of the middle turbinate bones ; and in both instances a distinct success was the result of the treatment. The penetrating fetor, the symptom which, above all, induced the patients to seek surgical aid, disappeared under the use of disinfectant and astringent injections, although these had been used previously to the operation for months, and years, without any effect. The patients afforded examples of what I have often observed in cases of ozæna fœtida simplex, viz., the nose congenitally narrow, accessible only to the smallest instruments, the passage of which was the signal for hemorrhage ; the vomer bent, and the turbinate bones on one or other side almost completely obstructing the passage. In the one case there was considerable injection and velvety swelling of the mucous membrane, with much discharge. In the other there was present the cicatricial shriveling, with formation of horny crusts, to which so much attention has been lately directed. I am far from asserting, or even daring to hope, that in this extirpation of the turbinate bones we have found a sovereign remedy for ozæna. As to the best method of performing the operation I cannot yet speak with certainty. At the present time I would recommend the following plan : A strongly concave gouge of the largest available size is introduced into the nostril and pressed backward twice or thrice, in the direction of the middle meatus, *i. e.*, pretty nearly parallel with the horizontal plate of the hard palate. As the gouge is pressed backward, its cutting edge should be made to act first inward and then downward. The semi-detached fragments of bone must now be removed with polypus forceps or other suitable instruments. If bleeding be severe the meatus may be plugged.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"The Disease of the Scythians" is a study on an interesting and little known subject, by Dr. William A. Hammond. It was reported by the Greek writers that the Scythians, owing to being so much on horseback, diminished and sometimes completely lost their virile powers. The same condition was noted by Dr. Hammond among some Indian tribes of the far West, although there it seems to have been at times artificially fostered, for ceremonial purposes. The subject is one still quite obscure, and merits further investigation.

——The treatment of procidentia of the uterus has generally been unsatisfactory. In a reprint from the *Trans. of the Med. Society of Penn.*, Dr. E. E. Montgomery describes a case completely restored by an operation which is a modification of that recommended by Le Fort, and appears to have positive advantages over any hitherto employed.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A MEDITATION ON MEDICAL COLLEGES.

Just how many medical colleges there are in the United States, we do not know, not having counted the announcements of new ones for several weeks. Of one thing we are certain—considering the kind of colleges they are, for the most part, there are too many of them.

A medical college, to do any real good, must have a number of extrinsic advantages. It requires a city of considerable size, from which to draw sufficiently varied clinical material; it must be in a locality where able men can obtain a good living from their practice, as otherwise they will not come to it as teachers; its organization must not be under the control of one man, nor must financial success be necessary to its existence. This last touches the white. It means that the corporation must be with ample resources to begin with. There ought to be a law in every State prohibiting the establishment of any medical college unless the corporators could show $100,000.00 paid up capital and an agreement to fund all profits for ten years!

A poor man is generally despised, whether he deserves it or not, but a poor medical college always deserves it. No professional men have a right to band together to set on its legs an impecunious institution. The history of all such enterprises is a long list of jealousies and backbiting, degrading competition for students, wretchedly superficial instruction, deficient anatomical and clinical material, servility in lecturing, a sham of an examination, and a lot of grossly incompetent young men turned out to prey on the community as doctors.

If by accident an honest man is on the faculty and exposes this miserable history, then comes a scene of slander and recrimination, which stains the whole profession with its inkiness.

A lamentable example of the kind has been recently shown by the Columbus (Ohio) Medical College. It graduated a man after *three weeks* attending at lectures, and in the face of the remonstrance of at least one member of the faculty. The matter leaked out through the latter, and a vile anonymous attack upon him was made by another member of the faculty, *in the columns of a Sunday paper*, written at his request, it appears, by some attorney of the size for that sort of work.

This happened at the Columbus Medical College. But it is a great mistake to suppose that that college is particularly to blame in this matter. It has been called a "disreputable establishment," but it is not a whit more disreputable than a dozen other colleges, East and West, that could be named. It did what almost all poor colleges, scrambling for a foothold, must do. It is easy enough, said Becky Sharpe, for a woman to be virtuous on five thousand a year; and the intimation she meant to convey, that it was a very different matter on nothing a year, is just as true, and a good deal more so, of a college. Such colleges cannot afford to repel matriculants by getting the reputation of being severe. Then there are always in this country a large body of men who are poor and ill-educated, and yet who want the degree of M.D. These are always on the look-out where they can obtain it at the least expenditure of time, brains, and

money. These are the bawds who are always tempting the poor young colleges to the prostitution of their honor ; and their poverty, if not their will, consents only too readily.

If there is any suggestion by which the establishment of new colleges could be checked, it would be a blessing to have it known and applied. If there is anything in the resources of intellectual toxicology by which we could speedily get rid of a dozen or two of those now living, we should hail it as a boon, and administer it right speedily.

ONE OF THE CAUSES OF SUDDEN DEATH.

For a long time already clinicians have been bothered to see persons die suddenly, either under the symptoms of embolism or heart-thrombosis, or under the symptoms of apoplexy. But when the post-mortem examination was made, to show the embolus or thrombus on one side or the hemorrhagic effusion on the other, no such things were found. Later observations demonstrated the fact, that the only morbid lesion found under such circumstances, was the ossification either of the coronary arteries, or of the cerebral vessels. This, however, seemed not sufficient to account for the sudden death.

Cohnheim, in his new edition of his celebrated lectures on general pathology (Leipzig, 2d edition, Hirchwald, Berlin, Aug. 1882), gives us, at last, an explanation of this fact. He tied the coronary arteries, and found, to his surprise, that without giving rise to any prodromic symptoms of debility of the heart, the organ came abruptly and suddenly to a stand-still during diastole.

We can see now how a gradually progressing sclerosis of the coronary arteries, for instance, will suddenly occlude these vessels totally, and cause instantaneous death. Certainly such cases do not happen frequently, as usually the ossification in one artery goes on more rapidly than in the other, and we have then premonitory symptoms of failure of the heart's action ; but often enough the morbid process progresses symmetrically, and then we have such a sudden death. The same explanation holds good for the similar conditions in the vessels of the brain, *i. e.* the large arteries.

TREATMENT OF SEQUELÆ OF FROZEN EXTREMITIES

The Imperial Russian Kankasian Medical Society mentions, in its protocols, 17, 1882, some of the experiments Dr. Lapatin of Tiflis made, while he was attached to the infantry regiment Eriwan, during the Turkish campaign in Asia Minor, 1877-1878. The soldiers had been greatly exposed to the influences of the extremely cold weather. L. noticed frequently, that after milder degrees of frozen extremities, for years, disagreeable pains and a very annoying pricking in the parts made their appearance from time to time, especially during the colder seasons, and on sudden changes of the weather.

He tried, at first, all the remedies usually employed for such a purpose, but without any permanent success, till he found in some old work a long ago obselete remedy, with the results of which he is very much satisfied. This consists in brushing the parts, preferably with a glass brush, with a mixture consisting of equal parts of dilute nitric acid and aqua menthæ. This is the old Rust's Frozing wash, only that the latter contained aqua cinnamomi instead of aqua menthæ. The parts are brushed over with this, in the beginning once, and later twice daily. After three or four such applications the skin assumes a brown color, becomes dry, and a superficial scab forms, which, when thrown off, leaves a healthy skin. Within one and a half to two weeks the disagreeable sensations, which frequently prevent soldiers from putting their boots on, disappear forever.

We know, from our own experience, however, a far better, quicker and still more reliable remedy, which we have never known to fail, no matter how much the parts may have been inflamed, if only mortification had not set in, and this is copaiba balsam. The same is thickly spread on a piece of linen or muslin, and the affected parts covered with it during the night, and a stocking put over the whole. In daytime

simply some of the balsam is spread over the parts. After one or at most two applications, the redness and all pains cease, and a few more applications do not only remove every residue of it, but they seem to impart a remarkably increased vital resistance to the parts against frostbite, if only common precautions are used. In the several dozen cases that came under our observation, this remedy, so applied, did not fail in a single instance, so that we have long come to consider it a specific in this annoying complaint.

Notes and Comments.

A New Antiseptic.

The *British Medical Journal* gives an interesting account of the discovery of the antiseptic properties of turf mould. It seems that some two years ago a man applied to Dr. G. Neuber, assistant to Professor Esmarch, in Kiel, with a laceration of the soft parts, rupture of the wrist joint and fracture of both bones of the fore-arm. It was dressed at the time with a thick coating of mould from the moor on which the man was at work and a rough wooden splint. When seen, ten days later, he appeared in good health, and when this dressing was removed, the wound was found free from suppuration, in some parts already united by first intention, and in others granulating in a satisfactory manner. It was found that the turf acted as a powerful deodorizer of fecal matter. It has been found to so effectually disinfect excretions from horses, that the same bed can be used for two or three months. The turf mould, reduced to a powder, is enclosed in gauze bags, which have been thoroughly washed in carbolic acid solution. The wound is first washed with carbolic acid or chloride of zinc lotion, or powdered with a little iodoform. The bag is then placed over the wound, over which a larger bag is adjusted, and both are retained in place, and an equable pressure kept up by a gauze bandage. The dressing was used by Esmarch in fifty-five cases, among which were seven resections and osteotomies, five amputations, twelve extirpations of tumors, and two herniotomies. The results were most satisfactory. In thirty-one cases there was no fever at all. In only five cases was it necessary to remove the dressings on account of local or general disturbance, and, as a rule, they were left in place for a fortnight. The advantages claimed for the mould are, that its absorbent power is so great that wounds remain perfectly dry under its use; that it absorbs the products of decomposition, and probably checks their formation; that the pads are very soft and elastic, easily adapting themselves to the surfaces of the limbs and trunk; and that turf mould affords the cheapest known antiseptic, since it costs only about one-ninth as much as the carbolic gauze (Listerian) dressings.

The Inheritance and Hygiene of Bright's Disease.

In the *Practitioner*, Dr. Joseph Kidd relates a remarkable instance of the hereditary nature of Bright's disease. A lady, aged sixty, one of a family of most temperate habits, died in 1860, of Bright's disease. One of her children died from the same disease in 1872, aged thirty four. Another died in 1873, aged thirty; still another in 1880, aged forty-six. In one case the disease was known to have existed for ten years, and in another there were all the symptoms and signs of advanced granular degeneration of the kidneys for seventeen years before death. Another child has had the disease for twelve years, and of her children (grand-children of case No. 1), two out of five have Bright's disease, one for the past ten years, and the other for the past nine years. In all of these cases great attention has been paid to hygiene, and its influence on the course of the disease has been most marked. Several times grave uræmic symptoms would supervene, but under appropriate treatment would pass off. Case two, who died aged forty-six, and who had had the disease for seventeen years, afforded the most striking proofs of the value of hygiene in this disease. During nearly all this time the urine was highly albuminous and contained granular casts; he led an active business life, but endeavored to take care of his health, leaving work every now and then, for long holidays; wore Shetland wool underclothing, and kept up out-door exercise. He was more careful than his brothers, and lived longer with the disease than they did. He often wintered in the South of Europe. In an evil hour he was persuaded to take a voyage to Alexandria in March, contracted dysentery there, and nearly died. Subsequently returning from Cannes, he crossed the Alps on the *outside seat* of a carriage, caught cold, dropsy of the chest came on, and he died en route. The whole experience of this family goes to prove that hygiene has infinitely more influence in prolonging life with, than has any known drug in curing, Bright's disease of the kidney.

"Catching Cold" from Wettings with Salt Water.

Dr. William H. Pearse writes to the *Medical Press and Circular* that he has been some thirty times around the world, in the latitude south of Capes Good Hope and Horn, in charge of thousands of people, and that he does not remember ever seeing illness caused by drenchings in sea water. He says: "Personally, I became indifferent to being drenched by the great seas breaking over the ship; sometimes I would change clothing, but as a general rule, I would not take that trouble, but remain wet and re-wetted. The top of a mighty wave would come on board and drench a crowd of people. I never myself took cold, and this same immunity extended almost as fully to the people.

As illustrating the seemingly slight circumstances on which health and disease depend, I may mention that, having always worn American cotton twill trousers, and being in Madras when the heat was great, I ordered a stock of brown holland trousers, as being cooler. I tried them over and over again, but always suffered in consequence—chills, or diarrhœa, or aching in the limbs. So marked and curious did this seem, that I used to speculate whether or not the linen texture had some special conducting power of the hypothetical vital conservative "energy" of the body! Be that as it may, of the facts of the danger of linen and the safety of cotton I was forced to believe, as I was also of the absolute safety of a wetting from sea water, and of the great danger of a wetting from a mere shower in Bengal or Guiana.

The Abortive Treatment of Gonorrhœa.

Believing that gonorrhœa is due to parasites, Dr. W. Watson Cheyne (in the *Lancet*) contends that the proper method to abort the disease is to destroy the parasites. The materials which he employed with the view of destroying the cause of gonorrhœa were chiefly iodoform and eucalyptus oil, and these he still uses. As injections are apt not to penetrate sufficiently far, and as their effect is only momentary, he combines these substances with cocoa butter, and makes them up in the form of solid rods about 4 in. or 5 in. in length, and about the thickness of a No. 10 catheter. These rods weigh forty grains each, and each contains five grains of iodoform and ten minims of eucalyptus oil. They are dipped into eucalyptus oil, introduced into the urethra, over the orifice of which a pad of boracic lint is applied, and outside this is a large piece of gutta percha tissue, the whole being fastened on by strapping, and retained for four or five hours, if possible. The cocoa butter soon melts, and a solution of iodoform in eucalyptus oil bathes the mucous membrane for some hours. Another rod may then be inserted, and a suitable injection be employed afterwards. This method is only of use, in his experience, before or during the inflammatory stage, and he employs it at any time till the inflammatory symptoms have disappeared, but generally within the first seven or eight days after the commencement of the discharge.

Incision of the Trigone.

The Edinburgh *Medical Journal* says that Sonnenburg, in *Centralblatt für Chirurgie*, states that this operation has been twice successfully performed in children. It is necessary that the calculus can be felt through the rectum, and that during anæsthesia it can thus be felt and drawn backward. The patient, being slightly narcotized, stands in front of an attendant, resting his head and shoulders in the latter's lap. The operator then introduces his forefinger into the rectum, pushes the peritoneal fold upward (apparently easily felt?), finds and grasps the stone, and draws the latter backward towards the gut. A vertical incision upon the stone is now made as far as the edge of the prostate, and the calculus is pressed through the wound. On the bladder resuming its normal position the incision is found to be very small. The attendant hemorrhage is slight, and the fistulæ healed in from 17 to 35 days. This method has the advantage of leaving the sphincters, the prostate, and the urethra intact, and seems to resemble the old method of Celsus. It has not yet been tried in the case of adults, and experience only can decide whether the fistulæ always heal as well as in the cases cited.

Prognosis in Diabetes.

The *Practitioner*, quoting from *Wiener Med. Woch.*, says that Dr. R. Schmitz, of Neuenahr, as a result of six hundred observations, says the question of prognosis is determined by (1) the earliness of the discovery and treatment of the complaint; (2) the strictness with which the anti-diabetic regimen is observed; (3) the etiological factors; (4) the age of the patient; (5) the degree of immunity the patient enjoys when he chances to use sugar-breeding food. In early cases the prognosis is favorable. Diabetes depending on central nervous lesions or on grave chronic affections is serious; depending on worry, pain and grief, or on over-use of sugary

food, it is less so. Gouty diabetes has the best prognosis of all. After the age of thirty the prognosis grows steadily worse. It is bad if sugar persists on an exclusive diet of fish and flesh. It is decidedly favorable if eggs, salads and mild cheese can be taken without breeding sugar, which only reappears when fruits, starchy roots, starch or cane sugar are taken.

Special Reports.

NO. X.—THERAPEUTIC PROGRESS.

(*Continued from page* 391).

CARBOLIC ACID FOR NÆVI.

In the *British Medical Journal*, Dr. Yeats reports a case of large venous nævus on the bridge of the nose in a child, which was cured by injecting, at one sitting, into different parts of the tumor, through one external puncture, five drops of carbolic acid and olive oil, equal parts. Care was taken to make firm pressure round the base of the nævus while the fluid was injected. The cicatrix that formed was very insignificant.

ANTI-ASTHMATIC MIXTURE.

The *Jour. de Med. et de Chirurg. Prat.* says that M. Huchard, of the Hôpital Tenon, employs the following, especially when the symptoms of bronchial catarrh are added to the attacks of asthma:—

℞.	Distilled water,	300 parts
	Iodide of potassium	
	Tincture of lobelia,	
	Tinct. polygala, of each,	10 parts
	Extract thebaic,	1-10 parts. M.

A tablespoonful to be taken night and morning.

ACONITE IN DYSENTERY.

In the *Indian Medical Gazette*, Dr. Owen reports the result of one hundred and fifty-one cases of acute dysentery treated with aconite. He was induced to look about for another treatment than the conventional one, with ipecac, on account of the nausea which often attends the latter, and which often drives hospital patients, especially, to rebel against a repetition of the dose. Dr. Owen gave the tincture of the British Pharmacopœia, which is of one-sixth the strength of Fleming's tincture. He gave one minim every fifteen minutes, for the first two hours; after that, one minim every hour. This would make thirty minims in twenty-four hours. Dr. Owen feels that his experience in one hundred and fifty-one cases justifies him in speaking quite positively in favor of the treatment. In his paper he gives a very good analysis of his results.

ELECTRICAL TREATMENT OF ANGINA PECTORIS.

The *Practitioner*, quoting from *Aerztl. Intelligenzbl.*, No. 39, 1881, says that Dr. Löwenfeld relates a case of angina pectoris, in which galvanization proved beneficial. The patient, a man aged forty-seven, was subject to attacks of the disease occurring every month or two. These were characterized by excited respiration, oppression, small, frequent pulse, sternal pain radiating to the left arm, and convulsive tremors of the limbs, and lasted about one hour. The heart was normal. The constant current was applied for one minute to each side of the neck, along the course of the pneumogastric. The sense of oppression was immediately relieved. Ten such applications in the course of three weeks were followed by complete freedom from the attacks for more than two years.

OIL OF PEPPERMINT IN ZONA.

Dr. Meredith writes to the Birmingham *Medical Review*, that he has found the oleum menthæ pip. more effective than any other form of anodyne application he has ever tried, in allaying the neuralgic pains so often piteous y complained of in cases of herpes zoster. These distressing pains, worse in elderly people, are complained of often when the eruption has disappeared; but painting the affected parts over with oleum menthæ pip. nearly always affords speedy relief. He has painted the oil over the eruption when it was out in a fresh, florid condition, and that with great relief to the patient. The value of this application in pains of neuralgic character deserves to to be better known than it is.

ERGOTINE IN TYPHOID.

The Boston *Medical and Surgical Journal* says that the treatment of typhoid fever by the subcutaneous injection of ergotine, as recommended by Dr. Duboné, continues to be noticed in *Le Journal de Médecine et Chirurgie*. The last case described is of a young woman, three to four months pregnant, in whom the treatment was begun on the eleventh day of the disease, when there was much tympanitis, diarrnœa, bronchitis, and dyspnœa, and when continuous delirium had given place to semi-coma. The morning temperature was 104° F. Ten centigrams of ergotine were injected daily for six days. The first injection was followed by a copious general papular eruption, of the size of a millet seed. The temperature fell to 101.5° F., and did not again rise above 103° F. The other symptoms underwent corresponding amelioration, and the temperature became normal on the seventeenth day of the disease.

Four days after the discontinuance of the ergotine the patient aborted, without any unfavorable symptoms. The fact that the abortion in this case took place so long after the omission of the ergotine, and the history of another case in which one and a half to two grams of ergot were administered daily for two weeks to a pregnant woman, without causing miscarriage, seem to confirm the harmlessness of this drug to persons who are pregnant.

CHLOROFORM AND NITRITE OF AMYL.

The Cincinnati *Medical News* says that in a recent communication to the *Medical Record* attention is directed to the use of nitrite of amyl in chloroform narcosis. It is stated in *Holmes' System of Surgery* that "nitrite of amyl has received the highest commendation as a means of combating chloroform narcosis. Its administration being by inhalation of the vapor, it can only be resorted to in some cases. Recoveries have unquestionably followed its use, but whether as a sequence or consequence is not so clear, and further observations are needed. It must be remembered that, although nitrite of amyl is a most effective remedy in one form of cardiac disease, its brilliant service is not due to its action on the heart, but upon the peripheral arterioles, spasm of which it relaxes, and that its action in lowering the blood-pressure is not favorable to its use in chloroform accidents." Experiments show, however, that hypodermic injections of five drops of nitrite of amyl, after complete anæsthesia and abolition of reflex action, with suspended respiration and a fluttering heart, are promptly followed by reaction of the pupils of light, resumption of respiration, and improved cardiac action, with ultimate recovery; so that the administration of this agent need not be limited to the inhalation of this vapor, but it may be given hypodermically. Again, although "its brilliant service is not due to its action on the heart," the result is similar, since, by the *vis a fronte* effect produced when the arterioles are relaxed, the cardiac current is drawn into the enlarged vessels, and stasis is prevented. Further, the statement that "its action in lowering the blood-pressure is not favorable to its use in chloroform accidents" does not seem to be borne out by the clinical experience. Dr. James L. Minor, of Rapidan, Va., reports a case in which a patient who had locomotor ataxia passed suddenly from a condition of usual health into collapse. There was a general pallor, with complete unconsciousness, and the arterial beat was imperceptible at the radial pulse, but faintly recognized at the femoral pulse. Here was evidently a lowering of the blood-pressure similar to that which occurs in chloroform syncope. The ordinary method of inhaling a few drops of nitrite of amyl was tried in vain, and then three minims were injected hypodermically. In a few moments the heart responded, and the pulse was recognized in the radial artery. In about half an hour the effects of the medicine seemed to disappear, when five minims were injected, with the result of producing action more vigorous than before. The patient lasted for nearly twenty-four hours, during which time amyl nitrite was frequently administered. As much as fifteen minims were given at one of the doses, when the "pulse became incompressible." So long as the vital powers were able to respond, the administration of the medicine was followed by a reaction which seemed marvelous.

Cases are also recorded in which impending death is said to have been conclusively averted by nitrite of amyl.

TREATMENT OF EXCESSIVE SWEATING.

In the Michigan *Medical News*, Dr. Currie says that for over thirty years he has used the following prescription, without a single failure, in sweats from whatever cause: Alcohol, Oj, sulphate of quinine, ℥j. Wet a small sponge with it and bathe the body and limbs, a small surface at a time, care being taken not to expose the body to a draught of air in doing it. In one case, a neighboring physician was poisoned while dressing a mortified finger. He suffered untold misery, and was drenched with perspiration for a number of days, and his life despaired of. When he saw him he ordered him to be bathed immediately in the above solution, and that this be repeated once in two hours. The third application stopped all perspiration, and convalescence began at once.

POMADE FOR COMEDONES.

The St. Louis *Medical Journal* says that Unna, in *Virchow's Archives*, recommended the following for comedones: Kaolin, 4 parts; glycerine, 3 parts; acetic acid, 2 parts, with or without the addition of a small quantity of some ethereal oil. With this pomade he covers the parts affected, in the evening, and if need be during the day. After several days all the comedones can be easily expressed, most of them coming out by washing the parts with pumice-stone soap. He reports uniform success from the use of this method. The *rationale* is based upon the view that the comedones are not produced by an accu-

mulation of particles of dust or dirt, but by pigmentary matter which is soluble in acids. It is a well known fact that comedones which accompany acne appear not only upon persons exposed to dust or careless of their persons, but also on chlorotic young girls in good circumstances. Besides, the discoloration not only exists on the surface of old comedones, but always descends to the lower parts. The same results as those obtained by the use of the above mixture can be secured by bandaging the affected parts for a long time with vinegar, lemon juice, or dilute hydrochloric acid. The author concludes by saying that the acids act like cosmetics, transforming the black color into a brown or yellow shade, and destroying it gradually altogether. They also produce a quicker desquamation of the horny bed which interrupts the exit of the comedones, and bring to the surface the glandular openings.

FUCHSINE IN BRIGHT'S DISEASE.

The *Canada Medical and Surgical Journal* says that this remedy has been used extensively by Dr. Renzi, of Geneva, given in pill form, .025 gram ($\frac{5}{12}$ grain) twice a day. There was at once a noted diminution of the albumen and dropsy. The urine was colored for some days. No result followed in one case. Similar experience was had by Brochut, of Paris. In every case albumen disappeared rapidly and entirely, the treatment generally lasting from four to six months. Dr. James Sawyer has used it mostly in cases of contracted kidney, with good results and no untoward physiological effect. It colors the mucous membranes of the digestive organs a deep red, and also the plasma of the blood, due to its presence, not to blood change.

SULPHUR IN WHOOPING COUGH.

According to the *Medical Press and Circular*, Dr. Luton recommends, in the treatment of whooping-cough, especially in the convulsive period, the administration of sulphur. Flowers of sulphur, 8 to 15 grains, sugar of milk, 16 grains. In ten powders, one every two hours, carbonate of iron should be given to keep up the strength, ten grains in the day. Coffee renders good service, and a vomitive should be given every two days. Belladonna, which has been considered the most efficacious remedy in this disease, has been given by Trousseau as follows: Ext. belladonna four grains, syrup of poppies and simple syrup, of each one ounce; one to eight teaspoonsful to be given in the twenty-four hours, according to age. Dover's powder associated with extract of hemlock has been frequently given with the best results in the formula: Dover's powder one grain, extract of hemlock in powder one grain, ginger in powder two grains, and sugar four grains, the whole to be given at bedtime, for a child of two years.

SPIRÆA ULMARIA IN PROSTATIC ENLARGEMENT.

Dr. J. Baugh writes as follows to the *Canada Lancet*:—

The use of this drug in the treatment of senile enlargement of the prostate gland has, in three cases, given me wonderful results. About ten months ago I was called to see T. B., æt. 68, in the city of London, and found him suffering from retention of urine. I had him put immediately into a hot hip-bath, the hot water coming well over the pubes, and administered a drachm of paregoric and twenty drops of Hoffman's anodyne every thirty minutes. He remained in the bath about fifteen minutes, when hot wet cloths were applied over the bladder. Nearly two hours elapsed before this method of treatment had the desired effect. After the bladder had been evacuated, I found on examination per anum, hypertrophy of the prostate. I then explored the urethra with a No. 10 catheter, found no obstruction, and the instrument glided into the bladder without difficulty. Two weeks subsequently to this attack, I was called again to the same patient. I tried my former method of treatment, but it failed. I also failed to introduce the catheter. Matters were becoming alarming, and I was about to send for professional assistance, when it came from another source, viz., an old woman. She volunteered the information that the patient wanted a dose of Queen of the Meadow (the common name for Spiræa Ulmaria) and that if he got it, it would cure him in quick time. She said some could be procured in a few minutes. I asked her to get it. It was brought, an infusion was made and half-a-pint given to the patient, and in fifteen minutes he desired to micturate, and emptied his bladder without difficulty. Since that time the patient has needed no medical or surgical aid to rid him of his old enemy. If he gets on a spree and his old trouble threatens him, he takes Queen of the Meadow tea and rejoices in being saved. In two other cases of this nature in which I used this drug, the results were just as satisfactory. I have tried it on myself in health, and find that it acts as a diuretic and astringent, since it sometimes causes smarting pain as the urine passes along the urethra. Its anti-spasmodic properties are very marked at the sphincter vesicæ, and I think much of its virtue in the affection named results from its power to overcome the contraction of the neck of the bladder arising from irritation in the prostatic region. It is my opinion that, in many cases of retention of urine from prostatic enlargement, the enlargement is not, *per se*, the main obstacle, but rather the spasmodic contraction of the sphincter vesicæ, as the result of a sudden congestion or inflammation of the prostate gland.

QUINIA SULPHATE IN PRURITUS.

Dr. Steele, of Denver (*Lancet and Clinic*), has found quinia sulphate, rubbed up with onl sufficient lard to hold it together, a specific for pruritus. He uses it in both pruritus ani and vulvæ. The nearer you get to the full strength of the quinine, the more efficacious it will prove.

PEROXIDE OF HYDROGEN IN SURGERY.

From the *Lancet* we note that the powerful germicidal properties of peroxide of hydrogen, the *eau oxygenée* of the French, have led MM. Péan and Baldy to test its practical value as a surgical dressing for extensive wounds and ulcerations of various nature, as an injection into sinuses and cavities, such as the bladder, the nasal cavities, and also in the form of spray, as a substitute for carbolic acid spray in major operations, such as ovariotomy. It was applied by means of compresses covered with an impermeable material, to prevent evaporation. During the dressings a spray of it was employed. The preparation used was absolutely neutral in reaction, and contained four or six times its volume of oxygen; but for the injection of sinuses or closed cavities a weaker solution was employed, containing only one or two times its volume of oxygen. The results obtained from more than a hundred cases have been most satisfactory, in grave as well as in trifling cases. Under the treatment recent wounds made with the bistoury or thermo-cautery, old wounds, even, when covered with gangrenous tissue, complicated with lymphangitis, or erysipelas, rapidly assumed a healthy aspect, granulating freely, with perfectly sweet, creamy pus. Chronic ulcerations rapidly cicatrized, and amputation wounds presented a strong tendency to heal by first intention. The general condition of the patients presented at the same time a marked improvement. The results are stated to have been quite as satisfactory as those obtained with carbolic acid. It has the additional advantage of being free from any toxic property, from any unpleasant odor, and of causing no pain. The results were especially satisfactory in some cases of varicose ulceration of the legs, intra-articular abscesses, ozæna, and purulent cystitis. In some remarks on the occasion of M. Péan's communication to the Académie des Sciences, M. Paul Bert, to whose investigations the French are indebted for most of their knowledge of the subject, pointed out that in the surgical use of this substance its influence was exerted in two ways, first by killing the organisms, and secondly by continually liberating oxygen on the surface of the wound. He insisted on the care which must be taken to secure its purity, since most commercial specimens contain a considerable quantity of sulphuric acid.

THE ACTION OF QUININE AND SALICYLIC ACIDS ON THE EAR.

The same journal says that in order to ascertain whether the noises in the ears produced by salicylic acid and by quinine are due to a congestion of the labyrinth, Dr. Kirchner has instituted some experiments in the pharmacological laboratory at Würzburg. The noise in the ears is sometimes accompanied by giddiness and deafness, which, usually ceasing when the medicine is discontinued, sometimes persists as a serious malady. Kirchner employed in his experiments rabbits, cats, dogs, and guinea pigs. His conclusions are that both these agents cause hyperæmia of the tympanum, which may go on to hemorrhage, and that the whole of the labyrinth participates in the congestion. It may become so intense that, if it lasts long, it will cause of necessity an alteration in the nerve filaments, and it may lead to exudation. This congestion he regards as produced by a vaso-motor mechanism. In this conclusion, however, another series of observations made by Weber-Liel and Guder does not agree. They observed carefully the symptoms produced in certain healthy individuals by a moderate dose (fifteen grains) of quinine, and noted, during two hours and a half, a gradual fall in the temperature of the external auditory meatus, corresponding to the diminution in the general temperature of the body. No hyperæmia could be detected in the meatus, the membrana tympani, or the handle of the malleus, either during this period or later. On the contrary, in five cases a slight hyperæmia which existed previously was found to disappear. The subjective noises in the ears come on at the end of an hour or an hour and an half, and continue for ten or twelve hours, while the deafness comes on one or two hours later than the tinnitus, and is greatest at the time that the general temperature of the body is lowest. Similar experiments were made with salicylic acid. Four or five grams of salicylic acid caused a diminution in the temperature of the external auditory meatus, which falls in the course of two or three hours to 95°. No indication of congestion could be discovered, and, as in the case of quinine, previous hyperæmia became lessened. Noises in the ear came on later and lasted longer than in the case of quinine. The deafness is very marked, and continued in some instances for several days, and in some cases in which there existed previous ear dis

eases, the loss of hearing was more prolonged, enduring in one case for nine months. In more than half the cases giddiness comes on a little after the subjective symptoms. Comparing the effects of salicylic acid and quinine, it appears that the former causes a less considerable depression of temperature and a more prolonged diminution in hearing. It is difficult, therefore, to ascribe the aural effects either to congestion or to anæmia, and if these observations are reliable, it would seem to be due to a primary nervous influence.

THE RATIONAL TREATMENT OF TAPEWORM.

Dr. Forbes Dick thus writes to the *British Medical Journal*: Allow me to express my belief that the male shield fern, properly administered, will expel not only the segments but also the head of the tapeworm. With due respect to high authority, I would submit that the adult dose of the Pharmacopœial liquid extract, as an efficient vermicide in cases of tænia, is not, as laid down in the *British Pharmacopœia*, from fifteen to thirty minims; nor, as usually administered to soldiers, one drachm; nor even, as Squire and others allow, eighty or ninety minims, but two drachms. The mode of administration should be as follows: A full mid day meal may be eaten, and a little bread, with tea, at 5 P. M. At 10 or 11 P. M. a binder is to be applied to steady the stomach; and on lying down in bed the following is to be taken. (Neither prolonged fasting nor filling the big bowel with fluid seem to be necessary.)

℞.	Extracti filicis liq.,		℥ ij
	Spiritus chloroformi,		♏xxv
	Pulveris acaciæ,		gr. xx
	Aquæ,	ad	℥ ij. M.

In the morning half an ounce of turpentine beaten up with the yolk of an egg should follow. The above large dose of the male shield fern is occasionally vomited, but I have failed to discover any deleterious effect contra-indicating its use. When vomiting happens, which is rare, on the following evening the same quantity should be taken in two doses, at half an hour's interval. The half an ounce of turpentine is more liable, especially in the tropics, to produce irritant symptoms. If active exercise be taken under a tropical sun after this dose, strangury follows, which there indicates the propriety of rest, to limit perspiration and prevent concentration of urine, and the drinking of bland fluids. A vermicidal effect being desired, surely one large dose of a remedy is more certain than several small ones.

Correspondence.

Information Wanted in Spirometry.

Ed. Med. and Surg. Reporter:—

I have been making observations and experiments with various spirometers, for the past three years, and hope to be able to write an article on the use of the instrument.

I wish to embody in the article the views and experiences of as many physicians who have used the instrument as possible, and hence, ask replies to the following questions:—

1st. Have you used a spirometer regularly, and how long a time, or about how many observations have you made with it?

2d. What form or kinds of spirometers have you used, and which do you regard as the best?

3d. What are the sources of error in the instrument, in your opinion?

4th. Have you ever made any systematic experiments as to whether the normal vital capacity can be increased beyond a certain limit, by the forcible and repeated use of the respiratory apparatus?

5th. What, in your opinion, is the value of the spirometer as a means of diagnosis and prognosis, and is this opinion the result of investigations you have made, or do you merely reëcho what you may have found in books on the subject?

6th. Please mention any articles on spirometry you may know of, other than those by Hutchinson, Hammond, or Guttmann.

Answers to any one or all of these queries will be duly acknowledged. A. H. Hoy, M.D.

[Our subscribers will aid in the scientific appreciation of this curative method by attention to the above.—Ed. Reporter.]

Butternut as a Preventive Remedy in Abortion—from Abroad—not New.

Ed. Med. and Surg. Reporter:—

History repeats itself in medicine; "honor to whom honor is due;" current vol. Medical and Surg. Reporter, Dr. Bell Morrelton, in *France Medicale*, has the following:—

℞.	Ext. hyoscyam.,		℥ j
	Ext. juglandis cinereæ,		℥ j
	Oil sassafras,		℥ ss
	Sodii bicarb.,		℥ ss
	Syr. simp.,		℥ vj. M.

Rezin Thompson, M.D., of Nashville, Tenn., read before the Davidson County Medical Society, October 5th, 1853, a paper on the use of ext. hyoscyam. and oil sassafras in some of the misfortunes attendant on pregnancy, from which I make the following extracts:—

"Having ascertained the controlling power which the remedy was capable of exerting over many forms of disease arising from morbid innervation, and looking upon most cases of abortion and premature labor as originating from that cause, I expected it to prove valuable in their treatment, and was not disappointed when I brought it to the test of experience. I have now used it in all cases of this kind in a large practice for twenty-five years, having more call

than usual in the same amount of general practice, my success having given me some notoriety in that line. I recollect of no case of failure where I was called in previous to occurrence of considerable expulsive uterine contraction." He gives the history of a number of cases.

He further says: to sum up the purposes for which I give the remedy. I give it in all cases of threatened abortion, when not caused by accident or severe sickness. I use it for all the nameless pains, aches, and disquietudes, attendant on conception and gestation. I give it to prevent and remove, when present, premature and erratic pains in the latter stage of pregnancy. In fact, in all cases in which I am previously spoken to, I put the patient upon its use a week or more before the expected confinement, for the purpose of removing any excessive nervous excitement of the general system, especially of the os uteri; thus preparing it to yield kindly to uterine contraction; and after delivery, I give it to soothe the excited system, and prevent those spasmodic contractions called after pains.

The following is Dr. Thompson's formula and name, viz:—

COMPOUNDED SYRUP, BUTTERNUT OR ANODYNE ALTERANT.

℞.	Ext. hyoscyam.,	℥ j
	Ext. juglan.,	℥ vij
	Oil sassafras,	℥ ss
	Bicarb. sodii,	℥ ij
	Syrup. simp.,	½ gal. M.

Sig.—Dose, one tablespoonful, as required to keep bowels soluble.

There is a striking similarity in the two formulæ, enough almost to lead us to think that our French brother had seen Dr. T's formula. Dr. Thompson, long since deceased, was a physician of keen observation and an original thinker. He published a work on fevers in 1856, which also contains articles on several other diseases, giving his peculiar views.

Gallatin, Tenn. T. M. Woodson, M.D.

Carbolic Acid in Blood Poisoning.

Ed. Med. and Surg. Reporter:—

In the interest of historical accuracy, I beg leave to call your attention to an inaccuracy of a paragraph that I have seen credited to your valuable journal.

After referring to the use of hypodermic injections of carbolic acid in blood poisoning, it is stated: "Nor was Dr. Déclat its originator; four years ago Dr. N. B. Kennedy, of Texas, used and wrote upon the advantages of these injections, and in April, 1881, he read a paper before the Texas Medical Association, in which he claimed priority of all others in its employment."

In a work now before me, entitled "De la Curation du Charbon, etc.," by Dr. Déclat, published in Paris in 1872, there are full directions given for the hypodermic injection of a solution of phrenic acid, with most interesting histories of cases of malignant pustule and other diseases cured by their means prior to that time, and especially during the siege of Paris.

These results had been communicated to the Academy of Science in the meeting of October 2, 1871, and are published in the *Comptes Rendus de l' Academie des Sciences*, 1871, 2me. *semestre*, No. 14. J. F. Corrigan, M.D.

New York, Sept. 18, 1882.

Stone in the Bladder.

Ed. Med. and Surg. Reporter:—

I notice in the August number of the Reporter a new way to detect stone in the bladder, by Dr. James McKenzie Davidson, as quoted from the *Lancet*. The auditory method may be a new one to him, but it is not to me. I received my knowledge of this method in the winter of 1878, while attending the surgical clinics of Prof. E. Andrews, in the Mercy Hospital of Chicago, who advised this method of examination in all obscure cases. C. T. Melsheimer, M.D.

Bluffton, Ind.

News and Miscellany.

The Chair of Operative Surgery in Berlin.

After Prof. Volkmann had also declined the chair of surgery in Berlin, for so many years occupied by Prof. Langenbeck, Prof. Bergmann in Wurzburg, has been elected, August 1st, A.C., as Professor of Surgery and Director of the Surgical Clinic of the University of Berlin. Bergmann is said to intend to begin his lectures the coming winter.

July 29th, v. Langenbeck said good bye forever to students and colleagues, in the amphitheatre of the surgical clinic. The room was beautifully decorated with flowers and with the finely executed bust of the beloved teacher. This bust will find its permanent place in the amphitheatre. The large room was too small, almost, for the many students, professors, physicians and friends of the celebrated surgeon; the earnest and sad words of Bardelsben and v. Langenbeck were a proof how severe this final separation was felt by the parting professor, as well as by those remaining. The *Deutsche Medizinal Zeit*, Aug. 3, 1882, adds to these remarks; "May the genius of Langenbeck continue to live in these halls, may the work he commenced and his ideas be further carried on in them, for the well being of suffering humanity, and to the glory and honor of medical art and medical science."

A New Grecian Pharmacopœia.

The *Pharmaceutical Journal* learns from a correspondent, that a Commission has just been entrusted by the Government with the task of elaborating a new Greek Pharmacopœia. The first official Greek Pharmacopœia made its appearance in the year 1837. In 1868 this work was reprinted, with an appendix, by Professor Landerer, describing the more recent remedies, and containing an etymological dictionary of names of botanical, zoölogical, and mineral substances, and a list of antidotes. This work is still in common use throughout Greece, as well as in Asia Minor, and also to some extent in Constantinople; but in Turkey, Dorvault's *l' Officine* is the work usually consulted.

A Good Opening.

The *Medical Times and Gazette* says that a correspondent writing from Puget Sound to the editor of the *Times*, of which place he gives a glowing description, says that professional services are rewarded richly. "I know of one young doctor who had the good luck to cure a grievous case of diphtheria soon after his arrival. He won a reputation instantly, and cleared $100,000 in eight years' practice."

The Latest Ligature.

The very latest in the wide field of antisepsis are (after the Kangaroo sinews, mentioned in one of our late numbers), carbolized nerves as ligatures. It is said of them, that they excell by their greater smoothness and durability, and that they are in every respect superior to catgut. The sciatic nerve of a calf was used as material. So far, experiments with these new ligatures were made on animals only, not as yet on men.

American Gynecological Association.

The American Gynecological Association held its annual meeting in Boston, Sept. 20, 21, and 22. The next session will commence in Philadelphia, on the third Tuesday in September, 1883.

Items.

—A very interesting and instructive medical congress was held in Seville, last spring.

—One year ago a needle entered the wrist of a young lady in Elmira, and the other day it was removed from the arm of the fellow who is her steady companion.

—Dr. H. L. Getz, of the class of 1874, Jefferson Medical College, has been elected to the chair of Physiology in the College of Physicians and Surgeons, Chicago.

—An imitation glycerine has been put on the French market. It is found to be simply a saturated solution of magnesia sulphate, with sufficient glucose to somewhat disguise the otherwise bitter taste.

—A painter who turned physician was asked why he had quitted his profession. "Because," he replied, "my former business exhibited my mistakes in too glaring a manner; therefore I have now chosen one in which they will be buried."

—The first acknowledged Sanitary Act in the statute-book of Great Britain was, in point of fact, a River Pollution Bill; for in the year 1388 an act was passed, imposing the very high penalty (considering the then value of money) of $100 upon persons casting animal filth and refuse into rivers.

—The Parisians deal energetically with milk adulterators. A posse of police lately waited the arrival of the morning's milk at Batignolles station, in Paris, and after witnessing from behind a loopholed wall the interesting process of "watering," pounced upon the delinquents, whom, with their deteriorated wares and a quantity of bicarbonate of lime, they carried off in triumph.

OBITUARY NOTICES.

MEDICAL INSPECTOR B. F. GIBBS.

Medical Inspector Benjamin F. Gibbs, of the United States Navy, died September 9th, at Trieste. He was born in New Jersey, entered the navy in 1858, as assistant surgeon, was attached to the steamer Memphis, of the Brazil squadron, and took part in the Paraguay expedition. In the following year he was detailed to the sloop John Adams, of the East India squadron, remaining on that vessel until 1862. In September of that year he joined the West Gulf blockading squadron, and was given charge of the hospital at the Pensacola navy yard. Thence he was attached to the steamsloop Ossipee, of the West Gulf blockading squadron, and Aug. 5, 1864, took part in the battle of Mobile bay. The following year he was on the vessel which chased the rebel ram Webb down the Mississippi. During a part of 1865 and 1866 he was attached to the school ship Sabine, going thence to the Ossipee, of the north Pacific fleet. In 1869 he was detailed to special duty in connection with iron-clads in ordinary at New Orleans. In 1874 he was at the Norfolk navy yard, and during the same year he was appointed fleet surgeon, south Pacific station. Three years later surgeon Gibbs received his commission as medical inspector, the rank he held when he died. His death promotes surgeon Edward S. Bogert and passed assistant surgeon John C. Wise.

DR. HIRAM NOTT.

Dr. Nott, who was at one time a very well known druggist, in New York city, died recently, of Bright's disease. He was 71 years old, and for a quarter of a century was proprietor of the drug store at the corner of Water and Fulton streets, whose business was established as long ago as 1800. He made much money, and 10 years ago retired to enjoy the pleasures of private life. He was exceedingly fond of a good horse, and his teams were well known on the road.

QUERIES AND REPLIES.

Subscriber, Austin, Nev. If any chloric acids are given while using calomel, corrosive sublimate may be formed in the stomach—

A. T. There can be no reaction between calomel and sugar of milk, unless the latter contains impurities.

MARRIAGES.

BROWN—SNYDER.—On September 28th, at the residence of the bride's sister, 419 North Thirty-third street, by Rev. Andrew Longacre, D.D., Dr. C. H. Brown, of Lancaster, Pa., and Miss Flora W. Snyder, of Philadelphia.

CURTIS—BOGERT.—In New York, Thursday, September 28th, at Zion Church, by the Rev. Arthur Brooks, Dr. B. Farquhar Curtis, and Eva Hawks, daughter of Edward C. Bogert.

GREEN—SPOONER.—At the residence of the bride's mother, Hempstead, L. I., Thursday, September 28th, by the Rev. Dr. S. Irenæus Prime, Charles L. Green, M.D., of Providence, R. I., and Maria S., daughter of the late Alden J. Spooner.

STARR—PARRISH.—On the 16th instant, at St. George's, Widmore, Kent, England, by Rev. Dr. A. R. Welden, Louis Starr, M.D., and Mary, daughter of the late Wm. D. Parrish, of Philadelphia.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

CASE OF TYPHOID FEVER.

BY E. T. BLACKWELL, M.D.,
Of Philadelphia.

The following case is reported because of the symmetry and fullness of all the usual symptoms; of some interesting phenomena connected with the brain and the digestive organs, and the remedial influence of the drugs used, some very freely, and others with exceeding reserve.

B. H. was affected with the usual prodromata of fever during March 24th, 25th, and 26th, and had decided paroxysms on the 27th and 28th. At noon on the latter day he was perspiring; his tongue was heavily coated white; the bowels sluggish; the pulse beat 90 per minute. He was under the influence of quinine, which was continued. He was to take, alternately with it, a diaphoretic mixture and one grain calomel till the bowels were opened.

At 8 A.M. of 29th the pulse marked 84; and at 5 P.M. 90. The patient complained of heaviness of the head, and slight tenderness and tympany of the bowels.

30th, 8 A.M. Skin somewhat congested; bowels tender and tympanitic; legs drawn up; bowels still closed; tongue white, with papillæ shining through; pulse 90; has had epistaxis. At 5 P.M. the pulse marked 92, and the temperature, then first taken, was 105°. There was more epistaxis during the afternoon. At 9 P.M. the pulse was unchanged; temperature reduced to 104°; indisposed to urinate. 31st. 9 A.M., pulse 96, temperature 102.6°; tongue moist and cleaner at the tip; report of high fever toward morning; increase of tenderness and tympany of the bowels; four liquid stools during the night. Noon, temperature 104°; 6 P.M., 103.4°; patient complains of stiffness of tongue and soreness at its tip.

April 1, 9 A.M. There have been eight liquid movements during the night; temperature, 1 A.M. 102.6°; the head is dizzy and aches slightly; pulse 93; skin dry; partially insensible to calls of bladder and bowels, and there is slight subsultus tendinum. Ordered Hope's Mixture, c. m. h. t. 2 P.M., there is intolerance of light and sound; one evacuation since morning. 4 P.M., temperature 103.6°; 7 P.M., 105.2°, and pulse 96. April 2, 2 A.M., temperature 104.1°; 8 A.M., 103.6°, and pulse 92; four movements in last 24 hours; there are no rose-colored spots; talks considerably, both waking and sleeping. 1 P.M., three movements since last report; tongue clean at tip, and moist, showing enlarged papillæ; head comfortable while in repose; pulse is weak; no apparent fever. 6 P.M., temperature 104.4°. 3d, 8 A.M., very thirsty, and restless during the night; talks incoherently; pulse 82; to take iodide of mercury, in accordance with suggestion of Liebermeister, in *Ziemssen's Cyclopædia*—hydrarg. protiodide, $\frac{1}{12}$ grain, with small amount of opium three times daily. 6 P.M., temperature 103.6°. 4th, 8 A.M., restless and incoherent during the night; several involuntary evacuations; at 5 A.M. he took $\frac{1}{4}$ grain morphia, and was afterwards quiet, but arose for a stool, of the pea-soup variety; keeps his knees drawn up, which tremble if unsupported; tongue tremulous and difficult of protrusion; pulse 92; at 3 P.M., 98, and temperature 103.6°; bowels having been many times moved, took $\frac{1}{4}$ grain mor-

phia, after which they were quiet; no red spots yet visible; abdomen moderately tender. 10 P.M. temperature 102.8°. 5th, 1 A.M., temperature 103.2°; 8 A.M., pulse 100; at noon, 104; the ears, which have been cold, are warm; nose still cold; sordes on lips; twitching of tendons; two movements in 24 hours; a few rose-colored spots are seen on the abdomen; has had morphia at intervals of 5 and 8 hours; rested well during the forenoon, but was occasionally noisy and incoherent; temperature 103.2°; 1 P.M., 103.4°; complains of pains in chest; and auscultation reveals sibilant and crepitant râles; a mustard poultice relieved the symptoms. During the week salicin has been used, as an antipyretic. To take, for the bowels, and to calm restlessness—

℞. Bismuthi sub-carb., ℥j
Spts. æth. comp.,
Glycerin., āā ℥ij
Mist. amygdalæ, ℥iv. M.

A tablespoonful every two hours.

The iodide of mercury, which produces its typical effect on the liver, was discontinued.

4 P.M. The patient has a fixed eye, and the muscles stiffen, as if for a general convulsion; the ears and body generally cool; pulse 102; temperature 102.6°; respirations 33.

6th, 9 A.M. Patient, while restless at times, throwing himself about and talking irrationally, upon the whole, rested well, and slept considerably. The bowels were quiet, and he asked for the urinal when it was needed; took his mixture, with a teaspoonful of brandy, every hour; temperature 101.2°; pulse 98; tongue moist, clean at tip, and cleaning in flakes upon its general surface; tympany and tenderness unchanged; surface cool; no thirst; three movements; had emplastr. picis to chest.

7th. Woke perhaps every fifteen minutes, showing some aberration till fully awake; not restless; bowels moved once; pulse 105; respirations 34. At 1 A.M., temperature 101.8°. The fits of nervousness are preceded by flushing of the face. The surface is cool. 2 P.M., pulse 96; at 4 P.M. 106, and temperature 103°; the face, neck and ears have a purple flush; there have been two evacuations during the day; he has been very restless, and full of tossings; his speech is incoherent and indistinct; his head aches, and the exacerbations of fever are preceded by coldness of extremities and of the body generally; his tongue is protruded with difficulty; the buccal mucous membrane and tongue are covered with mucus; the pupils of the eye are dilated, but respond to light; very restless. To take 5 grains salicine every 2 hours and continue the mixture; in the night was very nervous and out of his mind. 8th, 3 A.M. Has been very restless all night; the bowels moved three times; his pulse is fuller than for two or three days past. At 8 A.M. he commenced to sweat, the pulse being 91, and the temperature 102.2°. The eyes respond well to light; the mind is rational when concentrated, wandering when not; raises his body suddenly on his head and heels. 8 P.M., pulse 96; temperature 103°; respirations 24; took morphia, grain ¼; salicin omitted. 9th, 4 A.M., rested pretty well, becoming uneasy about two hours since, when morphia, grain ⅛, again produced tranquillity. 5 P.M., temperature 102.6°. 10th, 4 A.M. Has rested quite well, taking morphia at midnight; had a stool of good consistence, and makes considerable urine; the appetite is good; temperature 102.6°. 2 P.M., is very restless and incoherent; thinks he is in two pieces. 5 P.M., took morphia and camphor water; temperature 103.2°; rested well during the night. 11th, 5 A.M., pulse 90, of good volume and good resistance; temperature, 1 A.M., 101.8°; at 12.30 P.M. the same. Taking—

℞. Elix. ammon. valerianat.,
Tinct. cinchon. comp., āā. ℥ss
Aq. camphoræ, ℥iij. M.

Once every hour. Has had two movements. 12th. Rested well during the night, without morphia; temperature, 1 A.M., 101.4°; one movement; is perspiring; calls often and importunately for milk and fruit juices; took tablespoonful of ice cream. 2 P.M., temperature 101°; has chillness followed by fever and some delirium. 13th, 9 A.M., patient rested well, except at short intervals; took $\frac{1}{10}$ grain morphia at 5 A.M.; pulse 98; face slightly flushed; bowels once moved; temperature in the night 101°; in the afternoon he was cold, and fever and restlessness followed. 5 P.M., temperature 102°; took $\frac{1}{10}$ grain morphia and resumed salicin during the height of the fever; bowels again moved. 14th, restless, wakeful and delirious during the night; took morphia, grain $\frac{1}{10}$ at 1 A.M.; fever reported high. 12.30 P.M., temperature 102°; 5 P.M. the same; denies his identity and declares that he has a plurality of mouths; bowels moved; is to replace salicin with quinine and have half teaspoonful officinal solution of morphia when required; became restless about midnight, but did not take the solution till 4 A.M. 15th, 6 A.M. Sleeping since taking anodyne; pulse 91. 12 M., the same; temperature, noon, 102.3°; 5 P.M., 102.1°; 9 P.M., 100.8°. 16th. Rested well, taking

$\frac{1}{16}$ grain of morphia at midnight; quinia exchanged for Huxham's tincture of bark, to which was added the almond mixture and nervous sedatives; pulse 93; temperature at midnight 101.6°; 4 P.M., same; quinia resumed, as it seemed to have a favorable effect on the head symptoms; doubtless by reducing temperature. 17th. Has had a good night; pulse 84; temperature, 1 A.M., 101°; 2 P.M., 102.6°; pulse during afternoon 93. 18th. Rested well, taking $\frac{1}{16}$ grain morphia at midnight; pulse 90; temperature 101°; pulse and temperature unchanged during the day. 18th. Very restless until midnight, when morphia, $\frac{1}{16}$ grain, was taken; pulse range for day 90 to 95, temperature, 4 P.M.,103°. 20th. Rested moderately without morphia; perspiring in the fore part of the night and sweating freely in the morning hours; pulse 96; makes urine frequently, but the bowels have been rather close. To take 10 grains of quinine during exacerbation. Temperature, at 2 A.M., 103.6°; 4 P.M., the same; as also at ten; pulse 105. 21st. Pulse range for day from 92 to 98; temperature 102; passes vast amount of urine and is slightly indifferent to calls; had a costive stool. 22d. Very restless during the day; always indicates when he needs the urinal; respiration irregular, the breath being suspended several seconds at every third or fourth act; has had a very dry, hard stool; took $\frac{1}{16}$ grain of morphia, but continued restless till 3 A.M. His pulse then 92. Drinks less and voids less urine. Takes elix. valerianate of Ammonium, ℥xx, Huxham's tinct., ℥xl, brandy, ʒ ij, every hour. 6 P.M., respiration 20; regular; sleeping naturally; pulse 104; 9 P.M., 94; has had, unconsciously, a copious motion of the bowels, followed by a less one. Took a few doses of tincture krameria, and resumed bismuth and almond mixture; the patient rested well, the bowels giving no further trouble. The urine, which contains neither sugar nor albumen, continues very abundant; the calls very frequent and brooking no delay; pulse range from 96 to 102; temperature 102.2°. To take 6 grains of quinine per diem. 24th. Rested fairly, sleeping, especially towards morning, when he perspired for several hours; had two white, rather costive stools. Range of temperature 99.4° to 101.6°; sat up while his bed was made. 25th. Symptoms much as yesterday. 26th. A good night; one consistent motion; sweated freely during all the morning hours; temperature 98° to 101.6°. 27th. Repetition of yesterday. Taking the valerianate and Huxham's tincture. 28th. Costiveness continues; temperature 99°, pulse 84 to 90. 29th. Fever mostly gone; made two ineffectual attempts at defecation. To take pulv. rhei; at noon had great pains from the constipation, and from the straining for its relief, becoming very wild and ungovernable. By means of an enema of yolk of eggs and ol. ricini, with some manual assistance, the hardened masses were removed. To take elix. pepsin, bismuth and strychnia, and elix. valerianate of ammonia, alternately with syr. rhei aromat., every two hours.

30th. Temperature about normal; pulse 80; ordered—

℞. Ext. nuc. vom. fl., ℥xv
Elixir gentian cum ferri., ʒ ij. M.
Sig.—A teaspoonful every three hours.

May 1. Was restless in the night, but was relieved by aq. camph., of which he has taken a tablespoonful every two hours during the greater part of his sickness; his bowels have moved freely, and without great difficulty, although the constipation still continues in a moderate degree. Directed.

℞. Pil. ferri protocarb., ℈ ij
Ext. nucis vom., alc.,
Ext. gentianæ alc., āā ℈ ss. M.
Ft. pil. no. xl.
Sig.—Take one every three hours.

From this period his convalescence has been very rapid, his appetite being acute, and his digestion exceptionally good.

Attention is invited to the moderation, both in the frequency and range, of the pulse; to the remarkable vigor of the digestive organs; the amount of nutriment for many days being three quarts of milk, a whipped egg, and twelve ounces of almond mixture. The digestive power was equal to these extraordinary demands, except on one occasion, when the nurse acceded to his urgent demands, and gave, for the day, besides the almond mixture, a liberal amount of fruit juices, three eggs, and over four quarts of good milk. The resultant trouble was temporary, and not without its good effect in restraining his inordinate desire for food. The control of the disease by the remedies employed was rather phenomenal; the nervous symptoms being promptly ameliorated, the diarrhœa held in check, and the temperature kept within safe bounds. The final constipation I have before encountered, and it is probably due to loss of power in the muscles engaged in the peristaltic act.

—The Russian physician, Dr. Yavorski, who was in attendance on the late Ameer Shere Ali, will shortly publish an account of his journey in Central Asia.

LACERATIONS OF THE PERINEUM.

BY D. M. BARR, M.D.,
Of Philadelphia.

Read before the Northern Medical Society of Philadelphia.

I am to address you to-night upon the subject of the lacerated perineum. This is a subject upon which much has been ably said and written. The operation for its relief, has been so often and so accurately described, in works upon gynecology, as well as in reported clinics of prominent operators and specialists, that there would seem to remain but little of interest to offer you; and yet a matter of so great influence for good or evil to our race must be of some interest, by whomsoever considered, since every observer must view it in some new light.

In the hope, then, of encouraging some brother physician to offer to the suffering within his influence this simple but wonderful comfort, I will give you faithfully the subject as it has come to me.

My attention was first called to the operation for uniting this laceration by Prof. Agnew's paper, published in the Pennsylvania Hospital reports for the year 1868. The operation is here graphically described and beautifully illustrated; but I observed that, though the operation was advised by one whom I considered the best obstetric teacher of the day, yet it was performed only by a distinguished surgeon, with a strong corps of assistants. The operation seemed far beyond my reach. And some years later, when I saw my neighbor, an aged lady, obtain a new lease of enjoyable life, having for years been a miserable invalid, a burden to her friends and a loathing to herself, I thought the operator something more than man. But later one of my patients suffered more than I was accustomed to see, from a slight rupture. I asked a professor to operate; and my astonishment was great in seeing simply a paring of the mucous membrane surrounding the laceration, and bringing the pared surfaces together by the shotted silver suture, much the same as I had pared and brought in apposition the edges of the lacerated lobe of the ear, occasioned by the ear ring having been pulled through. I saw one beautiful operation by Prof. Goodell at his clinic, and took notes. I had no hesitation, thereafter, in doing the operation myself, modified according to circumstances and later teachings, and have never had reason to regret the undertaking.

Of the different steps of the operation I shall not speak, having nothing original to offer. I will say, let the clear and reasonable teachings of Emmett and Goodell, or others, be definitely and absolutely observed, in detail, and success, in all reasonable measure, must result. "Follow your guide and fear no evil," and your patients, perhaps too poor to obtain the services of a specialist, and too proud to accept charity, will pay you, and bless you for doing your own proper work.

I have no doubt many who commenced work as early as 1863-4, could to day give an experience somewhat similar to that which I will now relate.

In the year 1865 I was consulted by a lady who complained of continual diarrhœa, with inability to prevent the escape of flatus from the bowel. Upon inquiry I discovered a prolapsed uterus, and a ruptured perineum, involving the recto-vaginal septum slightly. What could I do. I then had never heard of the operation for relief. I simply replaced the uterus and supported with as small a pessary as possible, soothed the irritability of the parts by local applications, and held the bowels constipated as best I could; even for this she was grateful. Years afterward she was carrying out the same treatment, and refused my proffer to operate.

In the year 1870, I was accosted on the street by an elderly lady friend, fifty-five years old, whose misery was apparent in her countenance: "Doctor, what in the world can I do; I am in great distress; every step I take is in pain, and has been so for years." I gave her hopes, and upon inquiry, found a ruptured perineum, with a retroverted uterus. I told her of the operation for radical cure, also of the comfort a pessary might give. She chose the latter, and was greatly relieved; almost a new life was hers. I gave her directions concerning injections for cleansing, and bade her good bye. Five years thereafter she returned to me, in great misery again; I had used the soft rubber ring pessary; the rubber had decomposed in parts; the steel spring, exposed in places, had imbedded itself in the flesh; with great difficulty it was removed, the parts cleaned, and stimulating and disinfecting applications made to the parts. It was wonderful how speedily, and with what little annoyance or constitutional effect the trouble was remedied. The parts being healed, she again declined the operation, and a hard rubber pessary, as small as suitable, was used; this she wore with much comfort, until another five years, when she returned, the ring failing to support the parts; the ring was removed; the parts entirely normal, but relaxed. I

now strongly urged an operation, to which she assented, and last August the operation was performed, resulting in perfect union, and she is now enjoying a comfort unknown since the birth of her first born, twenty years before.

Last summer, a lady called upon me; she had been my patient since her marriage; some six years ago, at her first labor, in my absence (upon which I congratulate myself), she received a bilateral laceration of the uterus, also a rupture of the perineum.

In vain were all efforts to control the congestions and granular inflammations of that uterine neck; notwithstanding, a second child was born to her four years ago; her only comfort was while in gestation. During October of last year, assisted by Drs. Groff and McCreedy, the operation for laceration of the cervix was done, one week after which she had her first *painless* menstruation since the birth of her first child. On Saturday, November 7th, 1881, assisted by Drs. Groff and Heilman, the operation for laceration of the perineum was done; stitches removed on Wednesday, with every evidence of perfect union. And I am happy in being able to say a satisfactory result has thus far followed all the cases in which I have performed the secondary operation, encouraging me to repeat that, with close attention to details, as already laid down in the books, the operation may be performed, with every confidence, by any experienced obstetrician. I will say further, for the encouragement of those who may be short of assistants, in at least three other cases for whom I have operated, the only persons in the room were the patient, the nurse, Dr. Groff and myself.

But a matter of greater importance to every individual physician is the primary operation. This operation comes as an absolute demand upon every one who assumes to direct the act of parturition. The question of the proper support of the perineum is no longer dwelt upon in our schools, as formerly; indeed, in some it is not taught at all, the direction being, "If the head be delayed, place the forceps and pull it through, a few stitches will make it all right." How different this from the instructions I received; how well do I remember my respected teacher, in his lecture on the support of the perineum, folding a napkin to a soft, smooth surface, and placing it upon the distended perineum of a manikin, assuming a position to support against the advancing head. Gentlemen, said he, his face reflecting the anxious interest which should be felt at the moment when the future happiness and comfort of a suffering woman is staked upon rupture or no rupture, "how long should you hold your position here?" "I answer, one hour, two, three hours, if needed, until this head is extruded and this perineum saved. Remember the law; every perineum will properly distend, if time be given to prevent rupture." This early imbued attention to the perineum has saved many a one under my care. But in the light of our present knowledge it may be carried too far. Then, with ruptured perineum, we *bandaged the limbs* and HOPED; now we STITCH, *bandage and* EXPECT.

The question of "How long shall we wait," takes a new point of consideration. The condition of the child and mother comes earlier into the account. The powerful contractions which press the bones out of shape, and force the head into a long, projecting bog of congested blood and serum, must endanger the life of the child. I have seen, while faithfully carrying out directions "to wait at my post," a consulting physician draw a dead child through a ruptured perineum—a child lost, and the perineum not saved either. This was one of my earliest cases. I have often, since, thought how much better to have applied the forceps in time to save the child, perhaps, and spared the woman all that long agony. This was before I learned what I now so well know, that a light stage of anæsthesia, long before the profound sleep, would have spared all the pain, and added to the probability of an early delivery.

I can only answer the question of how long to wait, by the suggestion, where mother or child give evidence of exhaustion, apply the forceps, and consent to rupture the perineum.

And now, the perineum ruptured, what is to be done. It must be stitched. First, to protect the system against the probability of absorbing the vitiated secretions through a large, lacerated, absorbing surface. Second, to insure against the miseries pertaining to the lacerated perineum.

Again I will pass over the steps of the operation; they are to-day common property, "known and read of all men." My purpose is simply to encourage others to do the work; better teachers than I have studied and taught the details. I will only say, when carefully carried out, I have never failed to see satisfactory union follow.

As a part of my experience in the primary operation, and as a warning to do the work *well*, I give you my first case, a difficult labor, a consultation. Babe delivered through a ruptured perineum, and we placed two stitches. I knew nothing of the operation, and I soon discovered the attending physician knew but little more.

The parts were not carefully coapted, and failed to unite, but I hoped, at least, for as good a condition as might have been expected without stitches. I believe even this failed. The patient got up and about, but the parts discharged offensively, the system failed to strengthen, and in consequence of a further evil from exposure to sewer gas, an erysipelatous condition set up in the parts, with diphtheritic patches; in three days she died.

I will now give you my last three cases of primary operation:—

Case 2. Patient under my own care; primipara, young and strong; pains very vigorous; waited two hours; then, to save the child, placed the forceps and delivered; cord had been round neck and compressed; child breathed for a time, but finally ceased to breathe, after some eight hours. Perineum was stitched and made perfect, which remained intact through a second labor and birth of a large, healthy child.

Case 3. Patient thirty years old; primipara; parts firm and resistant, and head on perineum nearly one hour; explained to family the danger and the remedy; with their consent, delivered a healthy babe through a ruptured perineum; stitched and obtained perfect union.

Case 4. Patient forty-five years old; primipara; head delayed one hour; instruments were applied, with consent of family, and a very delicate child delivered in good condition, through a ruptured perineum, which was stitched and united perfectly.

In conclusion, I have the pleasure of saying, of the four last referred to cases, all but the first enjoyed the comfort of anæsthesia in their labor. That while they were unconscious of pain, they were never in profound sleep, and never failed to respond promptly to a question or a suggestion. The uterine contractions continued vigorous and regular throughout. The third stage was completed normally. There was no nausea, first or last. There was no hemorrhage, beyond ordinary, neither any other trouble. They awoke promptly, upon the withdrawal of the anæsthetic, and their getting up was without an untoward event; so far from being troubled by the operation for the laceration, neither of them knew of it until they were told; the last (No. 4), only when I came to remove the stitches, four days thereafter.

I have, therefore, to advise the forceps and the instruments for primary operation present at all cases of labor, especially in primipara, and to make the support of the perineum secondary to the welfare of the child.

ON THE FATAL INFLUENCE OF ANÆSTHETICS IN DISEASES OF KIDNEYS.

Abstract of a paper read before the Surgical Section of the American Medical Association, 1882,

BY LAURENCE TURNBULL, M.D.,
Of Philadelphia.

The writer dwells upon the great importance of attention to the condition of the kidneys by an examination of the urine when an anæsthetic is to be administered in a serious operation, or when a fatal result may be anticipated. The subject has not been dwelt upon with sufficient earnestness by surgical writers, or in works on anæsthetics; the first publication on this subject was by Dr. Emmett, of New York. The writer's attention has been drawn to this subject most recently, by finding that many deaths unaccounted for in any other way were due to this cause.

In the author's work (1879), he published "that the most dangerous condition in which to administer an anæsthetic is when there is renal disease, the blood being loaded with urea."

Again, before this Association, in 1880, it was stated by him, that it is now a well recognized condition, that in disease of the kidneys anæsthetics almost invariably produce coma and death.

He enumerates a considerable number of deaths from this cause, and some of them only of very recent occurrence. Also cases of death from chronic albuminuria, from twenty-four hours to eighteen days after the use of ordinary ether, as well as when hydrobromic ether was employed, but very few cases from chloroform.

After writing the above paper (March 1882), he received from Dr. Wm. F. Norris a pamphlet, in which was reported two cases of death supervening unexpectedly, after operations for cataract, which occurred in his practice (see full details in his pamphlet).

They presented four features in common: 1st. They were both anæsthetized with sulphuric ether; 2d. They entirely recovered consciousness; 3d. They died comatose, one in a few hours, the other eighteen days after the operation; 4th. In both cases a careful autopsy revealed no organic lesion, except Bright's disease of the kidneys.

The above cases before narrated, with those of Dr. Emmett's six cases of death, occurred from uræmic poisoning, while Drs. Wm. Hunt and Montgomery each had one case, verified by post-mortem examination. These go far to prove its fatal character, and need not have occurred if a proper and careful examination had been made of the urine before the anæsthetic had been given.

Dr. Agnew states, in his surgery, on the supposed contra-indication, "Ether may be given with impunity to persons suffering with renal disease;" but in his cases has he had any post mortem, to prove that death was not the result of kidney disease? As well remarked by Dr. Norris, "because fatal results do not follow in all cases, we have no right to shut our eyes to those where the employment of anæsthetics apparently leads to fatal disturbance of the renal functions."

The kidneys are the active agents in eliminating the ether from the blood, and if they are unable to perform this office, and the skin is cold, moist, and inactive, death will supervene by accumulation of mucus in the lungs, or congestion of the brain, in true Bright's disease of the kidneys.

A CASE OF TETANUS—RECOVERY.

BY W. B. POWELL, M.D.,
Of Natchitoches, La.

So far as noticed, there are three general indications for the treatment of tetanus:—

1st. To remove any local irritation which may appear to have excited the disease.

2d. To lessen the general irritability and spasmodic tendency.

3d. To restore the tone of the system.

If a thorn or any foreign substance be lodged in any part it must be extracted.

After an amputation, any spicula of bone which may have brought on the disease should be removed. A punctured wound should be dilated or cauterized, or a nerve divided, as the case may be.

On the morning of June 5th, 1877, Mr. C. B. T. came into my office, and consulted me in regard to his cook, a young woman, aged 19 years.

After closely questioning him, he *did* manage to tell me "she had a pain in her left shoulder and back;" her bowels were constipated.

I prescribed a cathartic and quinine, presuming the pains were due to malarial fever. At five o'clock of the same day he returned, and remarked that Miss. B. (the patient), still suffered. I gave him a sedative, and told him to bring her to my office the next morning (the 6th).

Promptly at the hour appointed the patient came to my office. I asked her to tell me her exact condition. Upon her attempting to speak I observed, to my great dismay, the characteristic "*sardonic grin*," which so well marks tetanus. It was not until then that I found out her true condition. This young woman, ten days previous to my first prescription, stuck a large splinter in the centre of the plantar surface of her right foot, to the extent of three-fourths of an inch; she tried to get it out, but did not succeed, so allowed it to remain, thinking it would "work out." Upon examination, I found the wound closed, and very painful on pressure, causing a severe prickling sensation. I enlarged the wound, and removed the splinter, and seared the part well with a small iron rod (one eighth of an inch in diameter), brought to a dull red heat. Severe tetanic spasms, to an alarming extent, at nine o'clock that night, which I quieted somewhat with chloroform inhalations. I remained with patient till morning. Ordered—

℞. Choral hydrat., ℈ ij
Sulph. morph., gr. ss.

which caused her to rest for a couple of hours, at the end of which time her bowels moved from the cathartic given two days before; she then slept one hour, when she was awakened by a spasm. I ordered ℈ j sulph. quin., dissolved in brandy and warm water, thrown into the bowels, also a hypodermic injection of ⅛ gr. morph, and 5 grs. chloral; left her asleep half an hour after. Morning of the 7th, 4 o'clock, ordered brandy ℥ j, chloral ℈ j, every hour, and the room kept warm and dark. I returned at 9 o'clock of the same morning; found my patient asleep, slight twitchings, jaws a little relaxed but somewhat stiff. Made no change in treatment; returned at 7.30 P. M.; found patient worse; had had spasms all afternoon; some fumbling, meddlesome person came in, opened all the doors and windows, which caused a great draught to blow on the patient, and at the same time ordered "Cockroach tea." I increased the dose of chloral and brandy, with an enema of ℈ j sulph. quin. and morph. ⅛ gr. Patient slept until 2 o'clock, A. M. (8th), when menstrual flux made its appearance. From that time the paroxysms became lighter, until the morning of the 13th, when she concluded to step out of doors. This piece of imprudence caused her trouble for a day or two. During the whole of the treatment I kept up strictly the third indication, restoring the tone of the system by wine, iron, quinia and diet, On the 25th of the month I discharged the patient, well.

I want to say a word in regard to "Cockroach tea." I was highly amused at the idea, and thought I would experiment a little.

The following is the formula: One dozen fat female cockroaches, put into a pint of boiling water (after being bruised), let stand a couple of hours, then strain well, add two tablespoon-

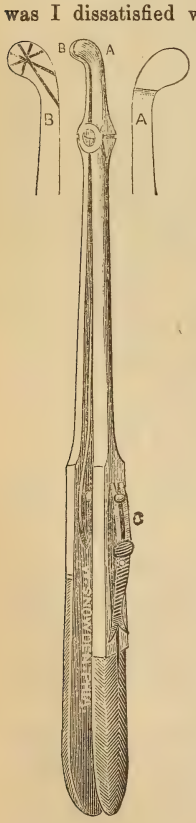
fuls of brandy and ℥j of crushed sugar; stir till thoroughly dissolved. Of this filthy stuff my patient was made to take two tablespoonfuls every hour. I being away upon one occasion, my chloral mixture was neglected for a whole day—discontinued—owing to carelessness, and during this time the "cockroach tea" was kept up by the "grannies." Upon calling next day I found the patient doing well.

Gentlemen of the profession, I ask, is there any virtue in the cockroach (male or female), or its active principle (Blattiden), in the treatment of tetanus?

A CONVENIENT ASEPTIC NEEDLE FORCEPS.

BY WILLIAM A. BYRD, M.D.,
Of Quincy, Illinois.

About two years since, when operating upon a cleft palate, I became satisfied that too many instruments were used, and more particularly was I dissatisfied with the number of handled needles necessary. To overcome this difficulty I had a pair of forceps made, similar in some respects to the one in the cut. By using a common trocar-pointed needle, from one-half to five-eighths of an inch in length, to carry the suture, with forceps bent at an angle, as in the cut, I found that I could pass the needle and then reverse the point and pass it through the opposite side of the palate from above, much more readily and quickly than the same suture could be carried by any handled needle with which I was acquainted. I have since used it in operating for cleft palate, laceration of the cervix uteri, and, in fact, all kinds of operations where needle forceps were needed, with great satisfaction. Being fastened with a slide catch, they are worked by the same motion of the hand that the surgeon is used to in using the common slide catch artery forceps. The wedge shape of the slide (C) permits the use of needles of varying size, and of their being gripped as tightly as necessary. One side of the jaw (B) has serrations, while the other (A) is faced with pure copper, which does not wear out so quickly as white metal. Being made of metal, they are not so bulky as forceps with wooden handles, and will not absorb septic matters, as the porous wooden ones do. The handles being file cut, are no more liable to slip in the hand of the surgeon than the more unwieldy instrument. I had several pair made before I got just what I wanted, but the accompanying cut represents the forceps as made by Mr. William Snowden, of Philadelphia. I do not wish a better instrument.



Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. W. H. DRAPER.

Reported by H. H. Seelye, A.M., M.D.

Rheumatism.

This case which I now show you, gentlemen, has already passed its most interesting period, but as it illustrates very well a very common disease, I will have the history read, and then I wish to make a few remarks.

History.—Patient is a young woman, 17 years of age, and is a native of Ireland. Does not use alcoholic liquors, gives no history of syphilis, and has never before had rheumatism. She does not know of any rheumatism in any of her family, except that an older sister has had two attacks. She herself has always enjoyed good health until December 2d, when she was attacked with pain in her shoulder, and afterwards in her knees, ankles and wrists. This was followed by swelling and great tenderness of the joints; and this was her condition at the time of her admission on December 8th. Her pulse was 90 per minute, respirations 16, and temperature 102.2°. Her urine was normal in amount and contained no albumen or casts; specific gravity 1.026. She is well nourished, and looks healthy, but her ankles and wrists are swollen and tender. The apex beat is felt in the fifth intercostal space and a little to the left of the line of the nipple. There is a systolic mitral murmur heard at the apex. The lungs show nothing abnormal, and the liver is of the usual size. Her bowels are regular. She says she had not been exposed to cold or wet before the attack.

This, gentlemen, is a very typical history of an acute inflammatory rheumatism, or as it is sometimes called, a rheumatic fever, occurring in a young, healthy girl, seventeen years of age. The first point in the history that attracts our attention is the fact as to heredity. She says she knows nothing of this disease in either of her parents, but she has one sister who has twice had attacks of rheumatism. This is sufficient, however, to show a tendency in her family to this malady; and you will almost always be able to find in the family history of a patient with rheumatism something to justify you in the opinion that there is a family inheritance of this

affection. In some families this is very marked. Where one or both parents have been subject to gout, you will sometimes find that the children are liable to suffer from acute articular rheumatism, that is to say, from attacks of true rheumatic arthritis. There seems to exist in the children of gouty parents a special tendency to vulnerability of the joints; and that particular form of catarrhal inflammation which is liable to follow from exposure to cold and wet, and to settle in some vulnerable part of the body, is very apt to be developed in these children.

The next point to be considered is the question as to what was the exciting cause in this case. There appears to have been no very striking cause here, for the attack came on suddenly, without any previous imprudence on her part. But you will usually, in young people, get a history of exposure to wet or cold. And the same conditions will also give rise to this as are liable to provoke a bronchitis, pleurisy or pneumonia. When, on the other hand, you come to adults, you will find that there is often something more than exposure to account for these attacks. For you will find them common in persons who have been given to excessive indulgence in malt liquors and wines, and in whom there exists, in consequence, a defective or perverted nutrition. Sometimes there is a distinct traumatic character in the etiology. And this is especially the case among the laboring classes and with those whose occupations necessitate fatigue of the joints. Such, then, are some of the exciting causes of rheumatism, and the predisposing causes are family inheritance, and the existence of a rheumatic habit of constitution, the acquisition of which may be accelerated by a vicious course of living.

The next point to which I will call your attention is the symptomatology, as it was demonstrated by the history of this case. She does not appear to have been very acutely attacked, for she had no chill, and the first symptom which she developed was pain in the shoulder, and then in the knees, ankle and wrist. And this was followed by swelling of the joints, and when she came in they were very tender and painful, and she had a moderate degree of fever. Since she was brought in the temperature has at no time risen to as high a point as it then was; and although she was then suffering very acutely, as soon as she was put to bed and the joints were protected and kept from moving by the crib which you now see, the pain subsided markedly, and she has since been free from suffering, and is now fairly comfortable.

In the history of her symptoms at the time of and since her admission, special note was made of the condition of her heart. This was done because in this disease you have always to fear cardiac complications; and you should, therefore, never omit to make frequent and careful examinations of the chest in every case of rheumatic fever which comes under your observation; for sometimes the onset of this complication is insidious, and it requires on your part special attention to the objective signs, in order to detect it at the earliest moment possible. Now this young woman had, on her entrance, a systolic murmur, heard most distinctly over the mitral valves and transmitted thence to the apex, and also to the other regions of the heart. But it was a murmur of no great intensity, and there was no accompanying enlargement of the heart, and no signs of pulmonary congestion, and no irregularity of the heart's action, nor any signs of endocardial disease other than the murmur. Now, therefore, the question arises, whether, in such a case, we have, in the mere presence of a murmur, sufficient evidence on which to base a diagnosis of cardiac disease, with a valvular lesion. As I told you not long ago, you must always seek for other subjective and objective signs in order to diagnose the existence of an organic disease of the heart; for a murmur alone is not a sufficient evidence. But in this case there were no conditions present to suggest a cardiac complication. For there was no dyspnœa, or præcordial distress, and no irregularity or unusual frequency of the pulse, and no palpitation or enlargement of the heart, and nothing but a soft murmur heard over the mitral orifice and transmitted to the apex, to suggest an endocarditis. Now, is it fair, under such circumstances, to say that the patient has endocarditis, or ought we to treat her for such a disease? There was a time when a murmur was considered as sufficient evidence of this complication, and blood letting was the appropriate remedy. So M. Bouilland was in the habit of bleeding a patient whenever he found a murmur; and when he did not find one, he bled the patient for the disease itself. And as a result, in his statistics on rheumatism, the proportion of cardiac complications was very much larger than that of any other practitioner. So clinical observers, since his day, have been accustomed to consider that he himself caused most of his murmurs, by reason of the extensive anaemia which repeated blood-lettings produced.

But we know now that simple anæmia is not the only cause of functional heart murmurs. For in the course of inflammatory disease we can frequently get a soft murmur at the apex, and less frequently at the base. But we do not look upon this as an evidence of endocarditis. but rather as a temporary murmur depending on a temporary cause, connected in some way with the febrile state and inflammatory condition. And I believe that this is the true explanation of a good many of the murmurs heard in connection with attacks of rheumatic fever. So, as I said, unless there are some subjective phenomena besides, I do not think it is safe to make a diagnosis of endocarditis in these patients. I feel reasonably certain, therefore, in this case, that the murmur which she had on admission, but which has now disappeared, did not indicate any serious endocardial mischief. And though you must always be on the watch for such a complication, you should never, I repeat, base its diagnosis on the mere presence of a murmur.

Now, I wish to call your attention to one other murmur commonly heard with considerable intensity over the base of the heart, and sometimes over all the præcordial region, in a patient who is convalescing from a rheumatic fever. This is a blood murmur, in the great majority of cases due, perhaps, to a poverty of red globules; and there is no other acute disease which seems to

have so destructive an effect upon the red blood corpuscles as acute inflammatory rheumatism. These patients are always more or less reduced; they have extreme anæmia, and this gives rise to a functional murmur, which disappears as their condition improves.

Treatment.—This young woman, after her entrance, was immediately put upon the salicylic treatment, and she was given ten grains of salicylic acid, every two hours, that is, at the rate of one hundred and twenty grains a day. And with her, as in the large majority of patients, the relief came within twenty-four hours. The pain, tenderness and the discomfort were lessened and the fever subsided, and I may say, in fact, that she entered upon convalescence within the first twenty-four hours after she was admitted. This speedy relief is not the uniform result of this plan of treatment, but it usually takes place within two or three days, at the most. I think it is fair to say that no other plan of treatment has ever been devised which is so uniformly successful as that by salicylic acid. There is another interesting fact in connection with this plan of treatment, and the alliance which is supposed to exist between acute inflammatory rheumatism and gout. For it is found that salicylic acid may be given with much success in the majority of cases of gout. And perhaps there is no other remedy, except colchicum, so good for this affection. This seems to suggest that both diseases have the same origin, and that the acid acts by neutralizing the poison upon which the existence of both depends.

Pneumonia.

The patient, Mrs. B. B., is a widow, born in Ireland, and a servant by occupation. Admitted December 6th. She has seven children, the youngest of whom is 20 years old. She is herself 50 years of age. She has never had rheumatism, malarial fever, or any other serious illness. She has recently been employed as a cook, and has been in the habit of getting up early in the morning to make the fire, and walking upon a cold, damp floor, with bare feet. So she thinks she caught cold four days before she came here, for at that time she began to feel sick, and then she became troubled with loss of appetite, nausea and vomiting, and with headache, vertigo, and a feeling of great prostration, and she could take no nourishment. For the first day or two she felt a pain across her back and between her shoulders. She has had considerable fever, and has grown steadily weaker. She says she does not use alcoholic liquors, but she drinks large quantities of tea. At the time of her admission her pulse was 120, respirations 44, and temperature 103.8°. She was poorly nourished in appearance. There was no œdema, but there was atrophy of the superficial areolar tissue about the breasts and under the clavicles. There was slight tenderness and pain upon pressure, in the epigastric and umbilical region. There was no cough and no eruption, and no intestinal gurgling or general abdominal tenderness. She at times raised a thick, viscid, rusty-colored expectoration. Upon physical examination, there was found to be but feeble respiratory movement over the right side anteriorly, and the expiration was prolonged. Posteriorly upon the right side, over the lower half of the lung, was obtained tubular breathing, and bronchophony and dullness on percussion. There were no râles.

Gentlemen, by looking at this chart which I hold, containing the trace of her temperature since she came in, you might easily guess at the nature of her disease. It is plainly a case of lobar pneumonia. You must have been struck with the peculiar character of the patient's subjective signs at the time of her entrance. For she did not complain then of pain, and she had no cough and no eruption, and she was suffering from nothing but a high fever and the prostration which accompanied it. Without a careful physical examination, you would probably have overlooked the true cause of this fever, and you would have taken it for a continued fever. But an examination of the chest reveals a lesion in the inferior portion of the right lung. With this there was a temperature of 104°, and a correspondingly rapid pulse and respiration. This high temperature continued throughout that and the following day, and on the seventh day of the disease there was also extreme feebleness of the pulse and of the systole of the heart, and great prostration. She was put upon large doses of alcohol, to relieve these alarming symptoms, and she received eighteen ounces of whisky in the first twenty-four hours, and the same amount in the second, and in addition carbonate of ammonia and digitalis were administered, and every effort was made to increase the strength of the heart and to tide her over until the time should come for a natural subsidence of the fever. On the night of the seventh day there was a decided fall in the temperature, and on the morning of the eighth it was down to 101°, and on the morning of the ninth it was subnormal. There is no question in my mind, therefore, but that the vigorous plan of treatment pursued during the acute period of the disease saved her life.

Now think for a moment of the difference between this plan of treating pneumonia, and the treatment by depletion and blood-letting which was pursued twenty-five years ago, before the times of Todd, who was the author of the plan of actively treating pneumonia, and to whom we owe the sthenic method of treating sthenic diseases. I do not doubt, and there is abundant testimony to prove the fact, that a young and vigorous subject will go through the whole course of this disease, even though there be a pretty high temperature, safely and with no medication. But when, in any case, there is good evidence, from all the symptoms, of great prostration, then you must not hesitate for a moment to stimulate the patient, no matter what is his age, and you must stimulate vigorously up to the time of defervescence. But you must not always, after the period of defervescence has arrived, be in haste to stop entirely the stimulating treatment, but the quantity of whisky should be gradually diminished from day to day. Thus, we are still giving the patient eight ounces a day, and she is not disagreeably affected by it, and she also takes still the carbonate of ammonia at night, and the digitalis as well. You must bear in mind the fact, that a patient is always weaker at night, and you should therefore give larger quantities of stimulants then than

throughout the day. There is a sort of a physiological cycle in our vitality during the twenty-four hours, which is to be remembered. It is found that the period of lowest vitality is during the twelve hours between six o'clock in the evening and six in the morning, or more definitely, between three and four o'clock in the morning. Then during the morning the vitality rises again, and continues to do so throughout the day, until evening, when it begins to fall again. For this reason you find that the greatest reflex disturbances occur very early in the morning, and this is the period of greatest reflex excitability. So asthmatic attacks are more likely to begin at this time than at any other hour of the day, and the same is true of epileptic fits. And a physiological proof of the same thing is in the fact that the larger proportion of births, as well as the larger proportion of deaths, occurs in the early morning hours. Therefore I say that the time for vigorous stimulation is during the later and the very early part of the day, and you should moderate the amount towards midday, and again increase it at night, and crowd it especially between three and four o'clock in the morning. It is very important that you should bear these facts in mind.

Apoplexy.

The next patient was a woman, forty-five years of age, a native of Ireland, married, and with no regular occupation. Admitted to the hospital December 10th. She has never had rheumatism, or malarial fever, or scarlet fever. Gives no family history of rheumatism or paralysis. For the past two years the patient has noticed that she was passing more urine than usual, and she often had to get up during the night to empty her bladder. She has had no œdema of the feet or ankles, or elsewhere. Six months ago, about ten o'clock one morning, while she was scrubbing the floor, she was suddenly attacked with paralysis, and complete loss of consciousness. She remained unconscious all day, and when she came to herself again, she found that she could not move her right arm or leg, and there was loss of sensation over the whole of the right side of the body. But sensibility was gradually restored. She was also aphasic for the first four days, but this, too, subsided by degrees. She has had no disturbance of vision, and no hallucinations, and she has not passed her urine or fæces involuntarily since her attack. But she has frequent desires to urinate, and passes large quantities of light-colored urine. Has had no bedsores from lying constantly on the paralyzed side. She complains of pain and soreness in the occipital and posterior cervical muscles. She has a cicatrix upon the tibia, which she says is due to an ulcer which she had there two years ago, and which healed of itself. She gives no syphilitic history. There have not been any muscular spasms or twitchings in the affected limbs, but for the past two weeks there has been complete rigidity of the parts, and the muscles are steadily contracting and producing a permanent flexion of the joints. At the time of her admission her pulse was 110, respirations 20, temperature 99.8.° As to her physical condition she was poorly nourished, had no œdema, and was paralyzed completely in her right arm and leg; but there was no loss of sensibility. There was a slight degree of facial paralysis, shown by a drawing up of the left angle of the mouth, and an inability to completely close the right eye, or to protrude the tongue without a deviation of it towards one side and by a constant dribbling of saliva from the mouth. There was still considerable impediment of speech, and she could not pronounce the labial consonants correctly. She was very emotional, and would cry at the least provocation. The radial and temporal arteries felt stiff and hard. A systolic murmur was to be heard over the aortic valve. The area of præcordial dullness was increased, and the apex beat was felt in the sixth intercostal space, and to the left of the nipple line. There was nothing unusual about the pulmonary signs. The urine contained no albumen or casts.

The history of this case, gentlemen, presents many interesting points, but not so much for anything in it which is unusual, as for the fact that it illustrates the characteristic features of the disease from which she is suffering. She is a woman not yet far advanced in years, but, as I have told you before, age is not to be measured by years. If you will put your finger upon her radial artery, you will find there a better evidence of senility than her years will furnish, for it is hard and cordy to the feel. This is a condition of the arteries which is common enough in advancing years, and it is generally looked upon as a senile change, and a degeneration of the structure of the arterial walls as the result of age. But it is a question whether it is fair to speak of this simply as a senile change, and whether it is not always induced rather by causes which are independent of years and of the ordinary life of the tissues. For you sometimes see it in very young people, and it is found to coexist with certain habits of life and with certain diseases, so that it cannot be regarded simply as a natural degeneration, and an indication that the full term of life has been reached in these tissues. It is found, for example with extreme frequency in constitutional syphilis, and perhaps the most serious consequences of syphilis is this arterial degeneration, for it is this which gives rise to the large proportion of aneurisms which occur in the deeper portions of the body in syphilitic persons. It is also a disease which appears to result from a general endarteritis in persons of a gouty habit, who are not advanced in years, but who have led what are called "fast lives," and have been accustomed to use freely fermented alcoholic liquors, and in persons who have all their lives been sufferers from that peculiar condition of the blood which is known as lithæmia, in which the blood is loaded with an increased quantity of nitrogenous products, and it therefore provokes an inflammation of the coats of the arteries. This accounts for the large proportion of stiffened blood vessels seen in young persons. The connection between this vascular degeneration and apoplexy is a very close and important one.

The history of this woman indicates that she had six months ago a cerebral hemorrhage into the left side of the brain, probably in the vicinity of the ventricles, and in the motor tract, and

in the vessels of the corpus striatum, but limited in extent, although large enough to produce a loss of power upon the right side of the body, which has not yet been recovered from. This hemorrhage may have been the result of a weakened condition of the arterial walls, or it may have been due directly to the bursting of a small aneurism, such as are liable to occur in the brain, or in other parts of the body where there is but little support to the walls of the blood vessels. These are called miliary aneurisms, and they form very readily in the cerebral tissue.

Another important point brought out in the history, and a very common occurrence in these cases, is the association with them of an enlarged heart and valvular disease. Here it was noted that the apex beat was in the sixth intercostal space, to the left of the nipple line, and the area of præcordial dullness was increased, and there was an obstructive aortic murmur with distention of the left ventricle, as is common in such cases. It is important to remember, however, that in connection with arterial disease you will almost invariably find an enlargement of the heart independent of any valvular trouble, and as a consequence of the increased power necessary for the heart to overcome the resistance caused by this arterial degeneration. It is quite necessary, in fact, that there should be cardiac hypertrophy. But you will find very frequently, as here, that the cardiac hypertrophy and dilatation are partly the result of diseased vessels, and partly the consequence of an aortic obstruction. Another condition commonly found in connection with apoplexy and arterial degeneration is the occurrence of the fibrous, atrophied kidney, or, in other words, a chronic interstitial nephritis. The evidences of the existence of this complication in this woman have not been accurately made out. But the fact that she passes large quantities of pale-colored urine is suggestive. And though her urine since she came in has been normal as to its chemical constituents, yet I will have frequent examinations of it made hereafter. For albumen is often absent in these cases, for a considerable period, and then it appears again. So I do not feel at all certain that we have not here that triad of phenomena which is so suggestive of a tendency to cerebral apoplexy, namely, diseased arteries, cardiac hypertrophy and granular kidneys. This is a triad which you will not unfrequently meet with, but when you do meet with it you may confidently expect to see a large proportion of the cases terminate in cerebral apoplexy.

Periscope.

Treatment of Acute Chorea by Massage and Free Administration of Nourishment.

Drs. James F. Goodhart and John Phillips contribute a valuable paper on this subject to the *Lancet*. This method of treatment, as suggested by Dr. Weir Mitchell, was practiced on several hospital patients. While the success was not marvelously great, the following advantages may be claimed for it, and the authors consider it a method of treatment deserving of trial: 1. A decided increase in weight; 2. Rapid subsidence of all the more violent movements, and it has happened that after two or three days' treatment a child, quite uncontrollable, has been able to sit up in bed, in a fairly quiet mind; 3. The extremities are no longer cold, and, as a further evidence of the good influence on the circulation, the pulse falls and becomes more regular; 4. Shampooing is a powerful sleep producer. There has never been any dislike of the treatment expressed, neither has there been any dyspepsia, as might be expected from the excessive feeding.

On admission, the patient is put into a padded bed. Milk only is given for three days; during this time the movements are carefully watched, grasping and articulating power noted, and bowels regulated. If the movements show no sign of abatement, massage is begun twice daily for fifteen minutes for the first seven days, and for twenty minutes afterwards. The diet-table for the first and second weeks is given below. The temperature and pulse are taken immediately before and after massage. The patient is weighed every week.

The following tables give the diet and results in one case, that of a girl aged 10 years, who was suffering from a second attack of chorea. She could not walk; threw herself about in bed; tongue bitten; no grasping power; cannot articulate; bursts into a paroxysm of shouting and crying if looked at; cannot swallow, the food dribbling out of her mouth. The other cases were treated on a similar basis.

Diet: At 5.30 A.M. half a pint of warm milk; 7 A.M., half a pint of milk, and three slices of bread and butter (each slice to weigh 1 oz.); 9.45 A.M., half an ounce of Kepler's malt extract, in lemonade; 10 A.M., massage (fifteen minutes), followed by half a pint of warm milk flavored with cinnamon-water; 12.30 P.M., rice pudding, half a pint of milk, green food and potatoes; 4.15 P.M., half a pint of warm milk, three slices of bread and butter, and one egg (half boiled); 7 P. M., half an ounce of Kepler's malt extract in lemonade; 7.30 P.M., massage for second time, followed by half a pint of milk immediately.

	After "	76	98.0°	74	98.0°

[3] Movements are already diminished; she can take milk with much less "slobbering"; articulation better.

[4] Tongue protruded much more regularly; tongue has not been bitten; no night terror.

[5] "Systolic" murmur very slight, and presystolic has disappeared; can articulate the word "Better" when spoken to.

[6] Systolic bruit has quite disappeared; can to-day articulate her name; takes all her food well; tongue protruded straight; grasping power weak.

[7] Weight 3st., 11lb, 12 oz.

[8] Last night some Kepler's malt extract was given which had been open for some time; this caused an epidemic of diarrhœa in those patients taking it. A mixture of opium and bismuth was given, and massage was stopped for three days.

[9] The systolic murmur has returned. In consequence of this illness she lost 1lb. 3 oz. (3st., 10lb, 9 oz.)

[10] Diet as before, except at 7 A.M., half a pint of warm milk and four slices of bread and butter; 12.30 P.M., chop (meat cut from bone, no fat), rice pudding, etc., 4.15 P.M., half a pint of warm milk and four slices of bread and butter, another pint of milk distributed over the twenty-four hours.

[11] All difficulty in swallowing has disappeared; systolic bruit scarcely audible; movements much less.

[12] Fed herself twice yesterday; can articulate ordinary sentences.

[13] Takes all her food well; sits up in bed; is able to hold a spoon.

[14] Muscles have become so resistant, from increase of their volume and tone, that massage is very difficult; sleeps well all night, and an hour or so after morning massage.

		Morning. Pulse.	Temp.	Evening. Pulse.	Temp.
" 13[15]	Before massage	76	99.0°	80	98.0°
	After "	70	98.0°	76	97.0°

All active movements have ceased, and she has now nothing but the occasional twitching usual in these cases. Massage was kept on for fourteen days longer, in the hopes that these too might disappear, but although they were materially lessened, and entirely ceased in three weeks, the diminution was scarcely marked enough to say that it was caused by the treatment.

We must insist on the fact that the treatment we advocate is for the acute stage of chorea, not the chronic, although (as will be seen from perusal of the above) much benefit may indeed be derived from it, even in these latter cases. "Massage," and the mode of performing it, is well described in Weir Mitchell's book, "Flesh and Blood, and how to make them." There are two or three essential points, however, to bear in mind: 1. Fifteen minutes twice a day, increased at the end of seven days to twenty minutes, is as much as the strongest child will bear. 2. After the operation the warm milk should be given and the bed-curtains closed, and all noise stopped; sleep then generally follows. 3. Neat's-foot oil, if used alone, often produces small boils, which cause the patient a good deal of discomfort. A mixture of an equal amount of olive oil will be found to obviate this trouble. 4. Care should be taken to give the Kepler's malt extract *fresh*. If any fermentation has taken place troublesome diarrhœa will probably result.

[15] Weight 3st., 12lb, 10 oz., an increase of 2lb in seven days.

Scurvy and Fresh Meat.

In commenting upon the report of Dr. W. H. Neale, Medical Officer of the Arctic steamer *Eira*, the *Lancet* says:—

The most interesting of Mr. Neale's observations, however, is that which relates to the absence of any symptoms of scurvy among the men—a fact which has led him to express the opinion that if men live on the flesh of animals indigenous to the country, even without vegetables, they will run very little risk of scurvy, so that, under such circumstances, lime-juice is not of much use. Curiously enough, while Mr. Neale is detailing his experience with regard to the prophylactic value of fresh meat against scurvy in the arctic region, Dr. Lucas writes to us from India, stating that the meat eating tribes of the northwest provinces are comparatively free from scurvy, while the vegetable-feeding tribes are not unfrequently attacked with the disease. This experience of both arctic and tropical observers, which does not stand alone, is so entirely distinct from European experience, that some solution of the apparent paradox is required. In a letter which we publish in another column, a correspondent points out that the statements of Mr. Neale and Dr. Lucas need not be considered as in any way upsetting our established views with regard to the disease, since, as he urges, meat is probably a scorbutic and an antiscorbutic article of diet, according to the period of time that elapses from the time of slaughter

to the period of cooking. Fresh muscle, as is well known, has an alkaline reaction, due to the presence of the neutral sodium phosphate; after rigor mortis has passed off the reaction becomes acid, due to the development of lactic acid; the neutral phosphate is thus converted into acid sodium phosphate. In hot countries the meat is eaten so freshly killed that lactic acid is not developed; in arctic regions the cold stops its formation; in European countries, where meat is usually hung, there is ample time for its generation. Thus in tropical and arctic regions the muscle plasma is alkaline when cooked, in European countries acid. If, therefore, it be true that scurvy is produced by a diminution of the alkalinity of the blood—a view originally put forward by Garrod and subsequently confirmed and extended by Dr. Ralfe—then we can conceive how fresh meat may be anti-scorbutic, while hung meat will have an opposite quality. Lastly, Mr. Neale is to be thanked for his suggestion of the use of blood as an anti-scorbutic. If its employment on future occasions should further prove its prophylactic value with regard to scurvy, we shall expect to see it extensively used by our mercantile marine, while under any circumstances, it introduces to the notice of travelers and voyagers a food at once portable, nutritious, and wholesome.

The Influence of Tobacco Smoking on Temperature and Pulse.

The *London Medical Record* says that, in order to ascertain the influence of moderate tobacco-smoking on temperature and pulse in normal subjects, Dr. J. V. Troitzky (*Vratch*, 1882, No. 7) made 600 observations in twenty-five persons, grouped into three categories, according to their constitutions: 1. Those of delicate constitution; 2. Those of ordinary constitution; 3. Those of strong constitution. The observations were made twenty times daily, from 9 A.M till 12 P.M. The author summarizes his results as follows:—1. In persons of ordinary constitution, on non-smoking days, the average daily temperature was 36.76 deg. C. (98.16 Fahr.), and the pulse 72.9; on smoking days, the respective figures were 37.02 deg. Cent. (98.64 Fahr.), and 89.9. In persons of delicate constitution, on non-smoking days, the average daily temperature was 36.6 deg. C. (97.88 Fahr.), and the pulse 69.3; on smoking days, the figures were 37.03 deg. C. (98.64 Fahr.), and 81.2. 3. In strong persons, on non-smoking days, the figures were 36.8 deg. C. (98.06 Fahr.), and 72; on smoking days, 37.02 deg. C. (98.64 Fahr.), and 82.6. 4. In persons of all three categories, the mean temperature and pulse on non-smoking days, were 36.73 deg. C. (98.11 Fahr.), and 71.55; on smoking days, 37.02 deg. C. (98.64 Fahr.), and 81.24. Expressing the conclusion between averages for smoking and non-smoking days, in form of geometrical proportions, we have the following figures: *a*, in ordinary persons, for the temperature 1007: 1000, and for the pulse 1230: 1000; *b*, in delicate persons, 1010: 1000 and 1170: 1000; *c*, in strong persons, 1006: 1000 and 1150: 1003: *d*, in persons of all categories, 1008: 1000 and 1180: 1000. [That is, tobacco-smoking produces a stronger influence on the pulse than on the temperature. The author considers even moderate tobacco smoking hurtful to healthy systems. Nobody ever denied that tobacco smoking influenced the temperature and pulse of a smoker; the question is only, whether this—at all events, not very considerable—influence is really harmful to the system.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the Annual Announcement of the Toronto School of Medicine for the current year.

——*Godey's Lady's Book* continues to furnish excellent reading for the household, pleasant and beautiful stories, matters relating to dress, household and the care of children, the latest fashions and handsome steel plates, all making a journal of a very satisfactory kind to the family circle. Published at 1006 Chestnut street, Philadelphia. Price $2.00 per year.

——A description of elephantiasis arabum, as it occurs in the Samoan Islands, is given in a reprint by Dr. Arthur C. Heffenger, U.S.N. He states that there is no correct description of the disease in medical literature. The only remedy seems to be excision, which is generally successful. The author describes a case where he removed a lymph scrotum weighing 35 pounds.

——We have received the Transactions of the South Carolina Medical Association, a volume possessing much interest. The President's Address, on "Primary and Secondary Reunion of Divided Nerves by Sutures," is a peculiarly valuable contribution to the literature of this important subject. A paper on the treatment of catarrh, by Dr. S. Baruch, is very practical and worthy of perusal, as are many others of the short and concise papers forming the volume.

——The whole miserable history of Guiteau and his actions has been of no practical value whatsoever to the medical profession; he has been fairly tried and executed, and the country is weary of reading about him. The notoriety which has been given to his base and aimless life can only be productive of injury by inciting other egotistical and weak-minded creatures to achieve publicity in some similarly unfortunate manner. Therefore we can have but little sympathy for the reprint from the *American Journal of Neurology and Psychology* on "The Autopsy of Guiteau." Hundreds of equally important and instructive autopsies are annually made in our almshouses, and are very little talked about.

——We have already told our readers of the reported success with which Dr. Robert Newman, of New York, has treated stricture of the urethra by electrolysis. We have now received a reprint from the *New England Medical Monthly*, of an article by the same gentleman, on "Stricture of the Rectum Treated by Electrolysis.' The author relates four cases in which he derived very good results from this method of treatment, and concludes that, "malignant and syphilitic causes excluded, stricture of the rectum may occur as a sequel of any inflammation in the tissues of the rectum itself, or by encroachment of diseased tissues surrounding the part.

"As no known treatment formerly employed has given satisfaction, the electrolysis deserves a trial, even if it does not cure always, and only relieves."

——*Lippincott's Magazine* for October has a very interesting table of contents. In the opening illustrated article, "Norfolk, Old and New," Charles Burr Todd tells how this city, "evidently intended by nature for a great commercial centre," is at last beginning to profit by the advantages of its position. "My Escape from the Floods," by Annie Porter, gives a vivid description of an overflow of the Mississippi river. "Bark Canoeing in Canada," an illustrated paper by "Kanuck," and "Camping on the Lower Wabash," by M. H. Catherwood, are sufficiently described by their titles. "My College Chums," by Henry A. Beers, is written with quiet humor. There are some very good things in the "Monthly Gossip," and the whole number is eminently readable, and among the best of the year.

——Dr. C. L. Dana read a paper before the New York County Medical Society, in 1881, in which he claimed that syphilis is a benign disease. Dr. L. Duncan Bulkley now comes out in an article (reprint from *Transactions of the New York State Medical Society*, 1882) advocating a directly divergent view, and basing his conclusions upon the analysis of 450 cases occurring in private and hospital practice. He sums up his conclusions in six paragraphs, one of which would seem to convey the true and rational position of syphilis.

"3. In a certain proportion of cases constitutional syphilis is a mild affection, even as the infectious diseases occur with varying severity under different conditions."

It is true that we know comparatively little of the minute history or phenomena of syphilis, but every general practitioner has surely seen cases in which the disease has been malignant, and again others in which it could readily be termed benign. The same pathological laws must govern syphilitic as well as other diseased conditions.

——The solution of the exudation in membranous laryngitis has always been considered a desideratum, but how to successfully do so has remained in many cases a mystery. Dr. Eugene F. Cordell, of Baltimore, has written a paper on the subject, in the *Maryland Medical Journal*, in which he advocates the erection of a sort of tent over the bed. Inside of it a pot of water is set to boiling, into which, every few minutes, a lump of lime is thrown. In one case (a very grave one) this procedure was kept up for five days, with recovery as a result. The point he makes is the desirability of the *continuous* use of the agent. He sums up his conclusions as follows:

1. It is simple, safe, economical and universally applicable.

2. It secures the most efficient form in which the application of lime can be made, and is that most nearly approaching the artificial solution outside the body.

3. It secures the *continuous* use of an agent, generally recommended intermittently and whose utility is unquestionable, and it is the only method that will do this.

4. It secures at the same time, and without extra trouble, the advantages of an atmosphere saturated with steam.

——The question of the efficacy of "*Non-restraint in the Treatment of the Insane*," is a very important one, from a humane standpoint. The idea of restraining human beings of their liberty, as though they were wild beasts, is repugnant to the dictates of humanity. Therefore, a reprint from the *Archives of Medicine*, of an article by Dr. J. C. Shaw, Medical Superintendent of King's County Lunatic Asylum, New York, entitled "A Second Year's Experience with Non-restraint in the Treatment of the Insane," is a very valuable contribution to the literature of insanity. For some years "non-restraint" has been the rule in many of the asylums of Europe; and those who advocate its impracticability will find their arguments forcibly refuted in Dr. Shaw's article. In the King's County Asylum seclusion is rarely used, and restraint almost never, while the results have been entirely satisfactory. One of the most important points in carrying out the system of non-restraint is to find occupation for the patients. This aids very much in keeping them quiet and more contented, tends to turn their

attention to a more normal train of thought, and in some cases prevents the rapid approach of complete dementia.

——Dr. L. Duncan Bulkley, of New York, who has an extensive and well deserved reputation as a dermatologist, presented to the last International Medical Congress a plan for reform ing the present confusing and unintelligible nomenclature and classification of diseases of the skin. A committee of five from various parts of the world was appointed to consider and report upon his plan to the next International Congress, in 1884. To illustrate the necessity for this reformation, it may be mentioned that there are no less than one hundred and twenty Latin names associated with eczema by different authors. The proposed classification is based upon that of Hebra, and to those who have any leaning towards dermatology will make interesting reading. If adopted it will tend to make this hitherto obscure branch of medicine intelligible and interesting to the general practitioner. It comes to us as a reprint from the *Archives of Dermatology*.

——Anything that contributes to our knowledge of "Bright's Disease" is particularly welcome, and possesses an unusual value to the profession. This insidious enemy of health is, par excellence, a disease due to neglect of hygiene, and as one would suppose, is to be controlled more by observance of sanitary laws than by any drugs now in use. Its diagnosis is remarkably obscure, more so in many cases than that of any other known disease, its symptoms being so varied that no approach even to general rules can be laid down for its recognition. It was supposed at one time that albuminuria was proof almost of the existence of this disease, but we now know that albumen can be found in the urine when no disease of the kidneys exists. Sir Henry Thompson, prominent among many others, has noted that violent cystitis or urethritis will produce albuminuria. Dr. T. A. McBride, of New York, read a paper before the New York Academy of Medicine, on "The Early Diagnosis of Chronic Bright's Disease," which is thoroughly deserving of perusal by all. After pointing out the fact that neither albuminuria nor the presence of casts are proof positive of the disease, he contends that "increased arterial tension" is to-day regarded as one of the most constant and valuable symptoms of Bright's Disease. While no doubt it is a frequent accompaniment or consequence of the disease, yet we fear he places rather too much stress upon it. On the whole, his paper is a most excellent one, and we wish we could afford more space to discuss its many merits.

BOOK NOTICES.

The Physician Himself, and What He Should Add to His Scientific Acquirements. By D. W. Cathell, M.D., etc. Second Edition. Cushings & Bailey, Baltimore, Md. 1 vol., pp. 207.

The education of a physician is not finished when he is prepared to contend against disease with knowledge and skill. Often the hardest task yet remains to him to learn, to wit, how to act toward the public and toward his colleagues, so that he may be successful as well as skillful, honored and prosperous as well as learned. For the want of this knowledge many a young professional man has been left behind in the race, and has taken a lower rank than his abilities deserved, or has left the profession in disappointment and disgust.

Neither text-books nor lectures supply this knowledge. If acquired at all, it is usually by hard knocks and painful experiences. Dr. Cathell has, therefore, addressed himself to a worthy task in endeavoring to equip the young physician for the battle of life with this indispensable outfit. He has done his work conscientiously and with a keen insight into the difficulties and exigencies which constantly arise in professional life. In some passages we would question his taste, in others the wisdom of his advice, but these are few compared to the great number wherein he evinces sagacity and discernment. We wish every graduate would read the book and ponder well its contents.

Nitro-glycerine as a Remedy in Angina Pectoris. By William Murrell, M.D., etc., Detroit: George S. Davis. 1882. Cloth, 12mo, pp. 78.

This is an interesting monograph on this powerful agent. Its beneficial effects in angina pectoris are illustrated by a number of striking cases. The relief is positive and immediate, but the use of the drug is, in some persons, followed by headache. An instance is given where even handling a small quantity brought on this unpleasant result. The author discusses its safety as a medicine, the best form in which to give it, the accessory treatment, and other points of interest.

Clinical Lectures on Diseases of the Urinary Organs. By Sir Henry Thompson. 6th London edition. Phila.: P. Blakiston, Son & Co., 1882. pp. 175. Price, paper, 75 cents.

These lectures are so well known and widely appreciated by physicians that they do not require any special notice at our hands. They are here put forward in a cheap edition, in clear type, with fairly good illustrations, and should be in every library which does not already possess them.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE USE OF TOBACCO BY BOYS.

The use of tobacco by growing boys is so generally recognized as pernicious, that it is extraordinary that more energetic measures are not urged upon those having the care of youth to prevent the habit. Already it has been prohibited in the U. S. Naval Academy, at Annapolis, in the U. S. Military Academy, at West Point, in the Phillips Exeter Academy, New Hampshire, and in various other enlightened educational institutions.

This was not the result of prejudice or hobbyism. If any set of men are free from these vices of learning, it is the naval surgeons, and it was especially from them, and particularly from Dr. A. L. Gihon, U. S. N., that this attack on the weed began. The indictment laid against it charged:—

1. That it leads to impaired nutrition of the nerve centres.

2. That it is a fertile cause of neuralgia, vertigo and indigestion.

3. That it irritates the mouth and throat, and thus destroys the purity of the voice.

4. That, by excitation of the optic nerve, it produces amaurosis and other defects of vision.

5. That it causes a tremulous hand and an intermittent pulse.

6. That one of its conspicuous effects is to develop irritability of the heart.

7. That it retards the cell change on which the development of the adolescent depends.

This is a formidable bill of particulars, and yet each of these charges is preferred by the best modern authority, and what is more, each is substantiated by an abundance of clinical evidence.

Testimony is also adduced from the class records of schools and colleges, which indicate very positively that the effect of tobacco on the mental faculties is deteriorating. The best scholars are not tobacco users; non-smokers take the highest rank in every grade; and whether we look at the exceptionally brilliant students, or compare the average of those who use and those who refrain from tobacco, the result shows the same.

With these facts staring us in the face, it becomes the duty of every schoolmaster and every parent to set himself resolutely against the beginning of this injurious indulgence.

It is, indeed, no easy matter to prohibit it successfully. There is a curious attraction about this nauseous plant, which has never been explained. A habitual consumer of it cannot explain its fascination. It has extended over the world with marvelous facility.

Nevertheless, we believe that the youth of America are intelligent and ambitious enough, in the aggregate, to be trusted. If the consequences of tobacco using are plainly stated by an authority that a lad respects, it will often lead him to drop the habit, or to refrain from beginning it, when threats and punishments would not. The latter he regards as an exercise of arbitrary power, the former appeals to his reason and good sense. It is the duty of a physician to express himself plainly on this subject, and he can only do so by condemning the habit in boys, at any rate.

DRAINAGE OF SEASIDE RESORTS.

So much attention has been directed to this question during the past summer, that it has assumed very large proportions, and constitutes, today, one of the greatest problems in sanitation.

Fundamentally, good drainage at the seashore is very difficult to procure; since one of its most essential requisites is a fall or decline in the land, so that gravity may aid the water supply in carrying off refuse.

At the majority of our seaside resorts the land is very flat, hence this great requisite is wanting.

Again, it is very essential that the sewer outlets should be so located that they can freely discharge their contents at any and all times.

Neither does this condition obtain, for in the majority of instances the sewers empty into creeks or waterways under the tidal influence, so that for a certain number of hours out of every twenty-four the water is rapidly backing up into them, thus not only preventing the escape, but actually blocking up the waste in the sewers.

To obviate this objection it has been proposed, at one of our summer resorts, to place floodgates at the mouth of the main sewer. But this would be no improvement, since these gates would act precisely as the tides, and would only serve to imprison the sewage during high water.

Again, the majority of our seaside municipalities are not overly blessed with worldly wealth, in consequence of which they are compelled to do what they do with as little expenditure of money as possible. Hence their sewers are very short, and discharge their contents, we fear, dangerously near the people. Now, at low tide, this matter, this refuse, lies exposed, upon the meadows, to the decomposing influences of sun and water. The bacilli of disease, about which we now hear so much, are generated or are charged with poison (whichever it may be), and when the wind blows from that direction, are wafted over the city, to poison the inhabitants thereof.

Drainage is a difficult problem, at the best, but when we take into consideration the two factors of want of influence of gravity and tidal effects, we have indeed a nut hard to crack. When to these two is added limited pecuniary ability, the case seems, indeed, almost hopeless.

The famous English watering place, Brighton, was recently arraigned by the London *Lancet*, on account of its drainage.

A careful examination by a sanitary expert developed the facts that an intercepting sewer of sufficient size for all refuse drained the other sewers into the sea; but when the tide was in, the water flowed into the open mouth of this sewer; in addition to which, a greater trouble was discovered, in the fact that the rain water was drained into this sewer.

Therefore, whenever a heavy rainfall occurred, during high tide, this sewer was completely filled with water, so that any gas which had accumulated therein was displaced and forced backward toward the dwellings, with a power that, to a certain extent, defied the intervention of traps, since this was the only outlet for the gases, that must escape. At first the corporation of Brighton refused to admit the truth of this report, but they finally appropriated several thousands of dollars to meet the defect, by providing efficient ventilation of the sewers.

This, no doubt, will make an improvement, but it cannot, we feel, radically cure the trouble.

When we remember that these bacilli are so very minute that six hundred and thirty-three million can be accommodated in a space the size of a head of a pin, and that they are so prolific that the progeny of one single parent would, in less than three days time, fill the oceans of the world, we must conclude that it is a very likely thing for some of these wonderfully active little bodies to escape the sanitary precautions of ventilators and traps, and obtrude their unwelcome presence into the homes of the residents.

We could cite numerous reports from various seaside resorts, during the past summer, to verify the statement that the whole system of seaside drainage is defective. It is true that the same statement will apply to many large cities, but in an especial manner is it applicable to the system of drainage suffering from such defects as we have pointed out.

The remedy is a great question, one upon which much intelligent thought must be expended.

There are, however, two grand, incontrovertible elements of improvement upon which we will touch.

1st. Removal of all excrement to a great distance from the settlements.

2d. Destruction of all disease germs that decomposition may generate.

The first can only be accomplished on level ground by the aid of pneumatic drainage, such as is now being experimented with in Paris.

The second must be attained by the universal use of such disinfectants as are capable of destroying the disease-carrying products of decomposition.

One way to accomplish this last indication is by means of a separate system of water supply to closets, which shall be furnished from reservoirs containing a *disinfecting solution*, so that each flushing of the closet may carry destruction to the disease power of these germs.

Such a system would be expensive, but so would the first, and we must remember that *health* is an expensive luxury to those who would surround themselves with all the comforts, conveniences and dangers of our modern civilization.

A whole volume could be written on this subject, but we desire merely to turn thought in this direction.

BOOK REVIEWS.

We once heard a very prominent publisher ask an editor whether he ever read books before reviewing them, and when answered in the affirmative, he expressed surprise.

That the publisher was correct and the editor verdant, is, unfortunately, all too true, and this to-be-regretted fact is prejudicial to both author and publisher, as well as really injurious and unjust to the purchaser.

Books are sent to journals for review, by publishers, in order that the fact may be made generally known that such a book has been written and is for sale.

Book reviews are read by intending purchasers, in order that they may be guided in their selection by the experience and mature judgment of an editor in whom they place confidence.

If books are reviewed without being read, one of two mistakes is apt frequently to occur.

1st. They will be unjustly condemned, or 2d, they will be praised more than their merits deserve. The truth of this statement is obvious. That many editors do so review books is a foregone conclusion, from the very style of the reviews.

That they do so thoughtlessly, to save themselves trouble, we firmly believe, and we are equally confident that they do not realize the injustice they are doing authors and readers by this negligence. The Review Department of a journal (of medical journals in particular) is a very important one, and cannot be slighted.

Of course, it is impossible for all journals to devote very much space to this subject, as some can, but all editors can at least make themselves familiar with the contents of books received, and divesting themselves of all prejudice, fairly and justly state the merits and demerits of the particular book under consideration.

If they do not do so, they should then confine themselves to the bare statement that such and such a book has been received; by which they will give the desired publicity to the publication, and leave the mind of the reader unprejudiced, to look elsewhere for a discussion of its merits.

QUERY—TOUTS OR EXAMINERS.

Under this title a prominent English Journal says:—

"The Medical and Surgical Reporter says that, 'in order to facilitate the admission of students and to aid the upward tendency of medical education,' the authorities of the University of Pennsylvania have appointed physicians, graduates of that school, in the different prominent cities, remote from Philadelphia, whose duty it shall be to examine candidates for admission into the Medical Department. By this means the applicant is spared the expenditure of time and money necessary to a trip to this city on an uncertainty. Truly considerate towards the students ! ! ! "

The word *Touts* is rather new to us, but we infer, from the tenor of another article in the

same journal, that it has reference to a means of soliciting patronage. We did not investigate the inner purposes of the University of Pennsylvania in making what seemed to us a great stride in the upward march of medical education, any more than we would question the meaning conveyed by the editorials of any well established and respectable medical journal. It would be folly for us or any other journal to dilate upon the standing of the University, which is so impregnable of itself as to need no defence When the authorities of such an institution see fit to take any action calculated to improve the standard of medical education, we must, perforce, as reasonable men, believe it to be honestly conceived and intended, until we have ample proof to the contrary. Such insinuations are out of place when applied to so venerable and so renowned an institution.

Notes and Comments.

Nerve Stretching.

In the *Lancet*, Dr. Augustus H. Bampton describes a case of supra-orbital neuralgia, in which the patient had used all known remedies without any relief, until the supra-orbital branch of the frontal nerve was cut down upon and stretched with a blunt hook, just behind its entrance to the supra-orbital notch. The relief was immediate, the wound healed by first intention, and up to one month after the operation, when he was discharged, there had been no return. The pain returned at intervals during the following winter, but considering the simplicity of the operation, the author considers that it should always be resorted to when other treatment fails, in this painful affection.

Intussusception in Infants.

Dr. W. R. Gillette, in the New York *Medical Journal*, states that he has succeeded in reducing three cases of intussusception in infants by the administration of chloroform, injections of warm water, and the application of massage to the mass felt through the abdominal walls. He knows of two other cases, where all the ordinary means failed, and reduction was effected by chloroform and massage. The children, in all these cases, were held, and the injections forced into them against all voluntary and involuntary efforts that they could make. In one case the gut had been invaginated forty hours, and in another for three days. In one case, the particulars of which are recorded, the water, after three or four bulbfuls were thrown in, was rejected. This was repeated constantly; it seemed almost impossible to get the gut to retain any water. Finally, an assistant resorted to massage (the infant being under chloroform). Immediately there was a roar of rushing wind and water, and a large amount of water passed in and was apparently retained. The child was laid down, warm bottles put around it, to rally it after the ordeal; the bowels were moved in a short time and a rapid recovery ensued.

Lead Paralysis from Contact.

In the *Gaz. des Hôp.* we find reported the case of a young man who was suffering from paralysis of the forearm. When in the army, whether in Algiers or Senegal, he always enjoyed the best of health in localities where numbers were dying around him—always having taken care to wear double flannels in the hottest countries. On leaving the army he became a carter for the transport of merchandise, and three weeks before admission had been transporting white lead. While loading his cart, one of the barrels burst, and he employed his left hand in endeavoring to save as much of the lead as he could. The hand and forearm were thus covered with lead. The next morning the extensors of the arm were paralyzed. It was a purely local paralysis, and neither colic nor any other sign of lead poisoning was present. He was treated by electricity.

Parturition Complicated with Whooping-Cough and Pleurisy.

In the Edinburgh *Medical Journal*, Dr. Wm. J. Beatty reports the case of a woman who, being pregnant, contracted whooping-cough from her children, three weeks prior to the expected confinement. On the night before labor commenced, she was seized with pleurisy. As soon as delivery was effected, she commenced to improve, and was entirely well eleven days after confinement. The Doctor, in conclusion, says: "This case caused me much anxiety, as the complications were really very formidable, and I confess I was rather surprised to find my patient recover so rapidly. Perhaps the pleurisy was cut short by the usual "loss" after childbirth, and, if so. are we right in not bleeding our patients in inflammation of the lungs or their serous envelope? Strange, too, that she lost her whoop."

Kolpokleisis for Vesico-vaginal Fistula.

The *Medical Press and Circular* says that Dr. R. Lomer, of Leipzig, in a reprint from Langenbeck's *Archives*, Bd. xxvii, 3, reports a series of thirteen cases of urinary fistula met with in the clinic at Heidelberg Two of these cases operated on terminated unfavorably. In the first of the two, after every method of operation had been tried in vain, that of "Episioplastik" was tried. This was an attempt to close the vaginal orifice by flaps brought from the thigh. The operation was only a partial success, union not being complete. The second was a case in which there was complete absence of vesico-vaginal septum and part of the urethra. The cure in this case was attempted by kolpokleisis, after the formation of a recto-vaginal fistula upon the sphincter ani. After repeated attempts the closure of the vagina was not only not effected but the urine still dribbled away. But what was worse, fæces and wind found their way through into the vagina, so that the artificial fistula had to be closed, and the patient was finally fain to depart unrelieved.

Hysteria.

The *Medical Press and Circular* says that a young girl, aged 20, was found one night, by the police, in an insensible state, lying on one of the benches of the boulevards in Paris. She was removed to the hospital, where she lay for several days in a sort of stupor, taking no nourishment and paying no attention to anything around her. Before waking out of her lethargy she gave birth, unconsciously, as she afterwards affirmed, to a child. Pins and needles were thrust through her legs and arms, but she gave no signs of sensation. All conceivable efforts to rouse her failed. When finally she roused up, she said that she did not remember anything that had occurred, and was surprised to find herself in the hospital, as she was alone in Paris, her parents residing in the country. The daily papers were much excited, and called her the "fasting girl," but the verdict will not fail to be hysteria.

Improvement on Tinctura Arnicæ, U. S. P.

Charles H. Hæntze, in the *American Journal of Pharmacy*, recommends the following as an improvement on the present way of making tincture of arnica. Take of arnica flowers 6 troyounces; alcohol 1½ pint; water ½ pint. First take the arnica flowers and rub in a mortar with 2 drachms of sodium carbonate, until quite fine, then take the powder and put in a 2 pound tin percolator of the Rosenwasser pattern, and percolate with the diluted alcohol, raising the reservoir about five feet above the percolator; the result is a quart of dark, clear and strong tincture, and as the quantity of carbonate of sodium is so small it would be hardly objectionable. This same tincture may be made by maceration, but as the latter takes up a great deal of precious time, the former way is preferable. Also the often seen precipitate does not appear in this process.

Functional Derangement of the Heart.

Dr. Zinsser, in the New York *Medical Journal*, refers to the case of a gentleman, forty-four years of age, in good health, who was suddenly attacked with distressing palpitation of the heart, without apparent cause, the pulse rising to 160 a minute. He was a moderate smoker and drinker. His urine was free from albumen at the time. Similar cases have been reported where mental excitement or worms have been the cause. Dr. Langemann considers that this condition might be induced by the introduction of strong alcoholic beverages into an empty stomach. Such a practice is occasionally indulged in by army recruits in Southern Germany, to deceive the examining physician.

Prolonged Use of Chloroform in Labor.

Dr. J. Wybrants Olpherts, in the *British Medical Journal*, relates a case of instrumental labor, in which the woman was kept completely under the influence of chloroform for over six hours, during which time the forceps were applied, craniotomy was performed, and the forceps used a second time. There was no excessive postpartum hemorrhage, no vomiting, no nervous shock. These good results he attributes largely to the use of chloroform, for he fears that ether would have a greater tendency to produce these troubles.

Influence of Light on Vision.

The *Lancet* says that M. Charpentier has been engaged in a series of researches to determine the quantity of light requisite to enable the eye to distinguish between two luminous points. He finds that with equal illumination and for the same distance the visibility of luminous points is directly proportional to their surface or to the square of their diameter. That with equal illumination and when of equal size the visibility of luminous points is inversely proportional to the square of their distance from the eye; and, thirdly, that when the luminous points are of equal dimensions, and at the same distance from

the eye, their visibility is directly proportional to their illumination. The eyes were in all the experiments exactly accommodated to the distance of the objects, and were free from astigmatism.

Acute Conjunctivitis Caused by the Electric Light

Dr. W. C. Rockliffe records, in the *Lancet*, the case of a man who was engaged in adjusting the carbon points of a lamp of 3000 candle power, without wearing the colored glasses commonly used to protect the eyes. As an almost daily occurrence the brilliancy of the spark causes more or less paralysis of the retina, or, to quote his own words, "he rarely is able to perceive the people walking on the footpath when descending the ladder from adjusting." Although this effect soon passes off, on this particular occasion, as he regained his power of vision (in about fifteen minutes) it was followed by rapidly increasing lachrymation, photophobia, pain and swelling of the lids, the whole symptoms being developed in thirty minutes. Having suffered from many slight attacks of a similar nature, he applied cold water, which previously had relieved him; but the pain and swelling increasing, I saw him the following day, apparently having suffered intense agony during the night. The lids of both eyes were very hot, red, swollen, and brawny, and level with the superciliary ridge, the swelling extending some little distance upward over the forehead. The pain was most acute in and around the eye. On raising the lids (which was a very difficult operation, the photophobia being so exceedingly intense) a considerable amount of lachrymal fluid gushed out. The conjunctival vessels were exceedingly large, and the eyeball a brilliant scarlet; cornea clear. All these symptoms yielded to a brisk purge and lead lotion in forty-eight hours. His fellow workman was similarly affected, but to a less extent.

Asses' Milk.

The *British Medical Journal* says that Professor Parrot, after extensive experience, considers it demonstrated that asses' milk is the best substitute for the human article. He has seen it bring about the veritable resurrection of infants. In the absence of a good nurse, a milch ass is the best substitute for infants. After it, in order, come the mare, the goat, and the cow. A she ass in full milk can satisfactorily nourish three infants of the average age of five months. In places where the goat can live free, and find the food it likes, it may be substituted for the ass. Asses' milk is particularly indicated in gastro-intestinal affections.

Poisonous Bullets.

The *Medical Press and Circular* says that M. Gros, of Paris, with regard to the complaints which were made of the use of poisoned bullets, explains that the construction of the modern breech-loading arms causes the bullet to convey with it a portion of the hydrocyanic acid which the explosion of the powder has caused to be accumulated in the barrel. Even if poisoning to a mortal extent does not take place, it is remarked that the healing of wounds is materially retarded by this circumstance.

News and Miscellany.

American Gynecological Society.

The Seventh Annual Session of the American Gynecological Society was held in Boston, Mass., September 20, 21, and 22. The meeting was presided over by the President, Dr. I. Addis Emmet, of New York. The Philadelphia representatives present were, Drs. A. H. Smith and Wm. Goodell. The address of welcome was delivered by Dr. Lyman, of Boston. Dr. Taber, of Washington, D. C., read a paper on "The Proper Use of Ergot in Obstetrics;" which consisted merely of a résumé of existing knowledge on the subject. With reference to its physiological action there was an agreement that it produced in a uterus already in labor a persistent tonic contraction, which finally became tetanic in character, and that this kind of contraction was diametrically opposed to the intermittent rhythmical contractions of the normal parturient uterus. The danger of long continued pressure of the head of the child upon the soft parts of the mother was then referred to, and also the liability of producing still-births by the use of the drug to overcome uterine inertia. He did not believe in its efficacy in cases of retained portions of the membranes, and thought that the labor of their extraction was very much increased by its use. He believed that the human race would be better off without than with ergot in the management of labor; certainly it should never be given to a primipara.

A paper on "The Treatment of the Pedicle in Ovariotomy," by Dr. R. S. Sutton, of Pittsburgh (who is absent in Europe), was read by the secretary. The paper, which was largely historical, closed with a consideration of the various conditions which influence success and failure, such as climate, avoidance of the operation in public hospitals, avoidance of septic diseases by the operator and his assistants, maintenance of strict cleanliness, etc.

AFTERNOON SESSION.

"The Care of the Perineum in the Second Stage of Labor," was the title of a paper by Dr. Theophilus Parvin, of Indianapolis. Some tearing of the vulvo-vaginal orifice in primiparæ is,

according to Duncan and Schroeder, inevitable; only 39 per cent., according to Schroeder, escaping rupture of the fourchette. The statistics of many obstetricians were then given, after which the author passed to the consideration of the causes, such as those relating to the pelvis, condition of the soft parts, etc. In order to reduce the accident to the minimum, or prevent it, it was the duty of the accoucheur to hinder the abrupt expulsion of the head of the fœtus, and permit gradual dilatation of the passages which it traverses. The various methods recommended for accomplishing this were then considered. When rupture was otherwise inevitable, it had been proposed to prevent the accident, by incision or incisions, but episiotomy should not be resorted to unless it was indispensable. Dr. Parvin advocated immediate closure of the rupture, should it occur, and the use of horse-hair sutures, which certainly were readily obtained, and probably were quite as good as any other material that could be used.

The next paper was read by Dr. Fordyce Barker, of New York, on "Leucorrhœa: Its Constitutional Causes and Therapeutics." It seemed to the author of the paper that the fact that leucorrhœa was not a distinct disease, but a symptom of many different and even opposite pathological conditions, had led to a neglect of its study, and practically to a forgetfulness of the fact that it not rarely originates from constitutional causes, and that when long continued it becomes itself a cause of local and important pathological changes. No writer during the last quarter of a century had considered it, except incidentally, as a symptom of some local disease, with the exception of Comty Stoltz and Robert Barnes, who had called attention to some of its constitutional causes. This was equally true of American, English, French, and German gynecologists.

For many years he was an entire disbeliever in the opinion of Tyler Smith, that leucorrhœa was in many cases the primary cause of morbid states of the os and cervix, and while now he was not at all disposed to accept the statement that this is the fact in the majority of cases, in the few last years he had been convinced that it was true in some. While all accept the statement that local and constitutional causes continue to develop leucorrhœa, yet he thought it might be questioned whether the latter be not too often disregarded in the present day, both in the diagnosis and treatment of this disorder.

Many of these constitutional causes, such as atmospheric changes, which induced general catarrhal affections, plethora in some, anæmia in others, all forms of defective nutrition and debility, etc., were well understood. The influence of nerve disturbance, as a consequence of defective nutrition, was, perhaps, not so generally appreciated, although most practitioners knew the fact that in some of their patients strong mental emotion was sure to bring on a troublesome leucorrhœa. Dr. Barker then considered the bearing which changes in the blood vessels of the uterus produced by pregnancy had upon this disorder.

He believes the most frequent error in the treatment of these cases is to be found in a disregard of the necessity of such remedial agents as would secure a healthy performance of all the organic functions, a neglect of the *morale*, and a routine prescription of some form of iron, which, under these circumstances, was sure to impair the appetite and produce headache.

Second Day.

The first address for the second day was by Mr. J. Knowsley Thornton, of England; the subject being "The relative value of Hysterectomy and of the complete removal of the Uterine Appendages, for the Cure of Uterine Fibroids." By "Hysterectomy," he means all cases where the uterine cavity is laid open and more or less of its walls removed with the fibroid. The conclusion reached was, that surgical aid is justifiable, even necessary, in a certain number of cases, yet there is the great mortality of between 30 and 40 per cent., after abdominal section, and a still higher rate when the uterine cavity is cut into or the supravaginal portion of the uterus removed. The operation must be considered a very formidable one. But thanks to American surgery, the brilliant conception of Blundell, in 1823, was made a recognized surgical procedure by Battey, in 1874, and from the labors of others, hysterectomy has been rendered less formidable than formerly. Statistics show that the removal of the uterine appendages is attended by less immediate danger to life than other operations for the removal of uterine fibroids. The operation must be done thoroughly, mere removal of the ovaries being useless; still less useful the removal of a portion of them.

Dr. Goodell took part in the discussion which followed the reading of this excellent paper.

The President then delivered his annual address, the subject being, "A New Method of Exploration, with the pathology and treatment of certain lesions of the female urethra." After showing the inexactitude of present means for examining the female urethra, Dr. Emmet passed to the description of the new method of exploration, which formed the basis of his address.

It was some six years since he devised the plan of making a button-hole-like opening in the female urethra, for the purpose of making a diagnosis and also for facilitating any operative procedure. In the second edition of his book he had entered into the subject at considerable length, but during the last two years he had given it very careful study. The method described he regarded as the only one within our knowledge which fulfilled every indication, was safe, simple, and within the scope of any one possessing the least degree of surgical dexterity. It was as follows: administer an anæsthetic, place the patient upon the left side, and use a moderate-sized Sim's speculum for bringing into full view the vaginal surface covering the urethral tract.

He had devised an instrument with which to make the opening into the urethra, but it had not yet been perfected to his satisfaction. It operated much on the plan of the ordinary scissors used for cutting button-holes. The operation could be readily performed by means of

tenaculum, knife, and straight-pointed scissors, with a block-tin sound, of size sufficient to place the tissues upon a moderate stretch, within the urethra. The opening should be made in the median line, forward to within one-fourth of an inch of the meatus, and backward nearly to the neck of the bladder. The neck of the bladder should never be involved in the incision. The line along the vaginal surface should be nearly one-third longer than the one through the urethral mucous membrane, and it was important that the chief difference should be at the end of the line from the neck of the bladder. If the opening was simply for exploration, it might be closed without delay, as in vesico-vaginal fistula. The advantages claimed for the method were that the whole of the canal could be fully exposed; that it was safe, and could be applied by any one possessing ordinary surgical dexterity; that, if properly performed, control over the urine will not in the slightest be impaired; that no difficulty has been experienced in closing the urethral opening afterward; and that no difference has been appreciated in the passage of the urine after the operation. It is not intended to supersede the formation of a vesico-vaginal fistula for the treatment of cystitis or removal of stone.

AFTERNOON SESSION.

"Notes on twenty-one cases of Extra-Uterine Pregnancy," by Dr. T. G. Thomas, of New York, was the first paper read. His experience from these cases caused him to formulate the following rules:—

First.—If the diagnosis be well settled before the fourth month of gestation, he would destroy the life of the fœtus by electricity, in preference to all other methods.

Second.—Should the fourth month of gestation have passed and surgical interference be called for, laparotomy, or, with the tumor low down in the pelvis, elytrotomy, should be preferred to electricity.

Third.—Should the pregnancy be abdominal, the practitioner might watch and wait until full term, and deliver by laparotomy or by elytrotomy and the forceps, or manual delivery.

Fourth.—Should the full term be passed and the fœtus be dead, wait and watch, and aid nature when she demonstrates the outlet by which she desires extrusion to be effected. If bad symptoms, under these circumstances, at any time develop, perform laparotomy, under strict antiseptic precautions.

Fifth.—Should rupture of the fœtal nest have occurred before diagnosis have been fully made, wait and see whether nature is powerful enough to overcome shock, to control hemorrhage, and further, if the patient is going to escape the dangers of peritonitis and septicæmia. If these favorable results do not occur, if hemorrhage is about to destroy the patient immediately, or if septicæmia attacks her later, laparotomy, followed by antiseptic cleansing, should be promptly adopted.

"Electricity in Extra-Uterine Pregnancy." Dr. H. J. Garrigues, of New York, followed with a paper on this subject. He claimed that experience has proved electricity to be an efficacious and safe agent to arrest extra-uterine pregnancy during the first three months, and perhaps after it has advanced into the fourth month. It seems to him probable that it may be useful at any period of fœtal life.

Third Day.

The morning session was opened with a paper on "The Influence of High-heeled French Shoes upon the Female Form, and upon the Relations of the Pelvic Organs," by Dr. Samuel C. Busey, of Washington, D. C. The paper was discussed by Drs. Barker and Thomas, of New York, who had been unable to trace any serious results, upon the pelvic organs, arising from wearing high-heeled shoes.

Dr. T. M. Drysdale, of Philadelphia, read a paper on "The Ovarian Corpuscle; its Origin and Characteristics." The author believes that the cell called "ovarian granular cell" is almost invariably found in the fluid of ovarian cysts; it is distinguished from other cells by its appearance and its behavior with acetic acid. It may be found in cysts in other parts of the body, but when found in this locality it is pathognomonic of ovarian disease. It differs from any other known granular cell found in this abdominal cavity.

This paper was prepared in answer to opposite views expressed by Dr. H. J. Garrigues, at the last meeting of the Society.

The discussion was opened by Mr. Thornton, of London, who thought there was not at present any basis to stand upon, concerning the origin of the ovarian cell, because of the very great difference of opinion, among expert observers, as to what a cell is, and how it grows. Although he had not devoted special attention to the subject for some time, he long ago reached the conclusion that the nucleus, perhaps, was the first, and not the last element; and that the cell was developed afterward. Of course that view struck at the basis of much that Dr. Drysdale had said, with regard to the origin of the cell in question. Whether it was called a cell or not, he had, long before Dr. Garrigues read his paper, concluded that it was a nucleus of a rapidly degenerating cell of the cyst membrane. With reference to the question of the action of reagents, upon which Dr. Drysdale relies so much, it seemed to him that the reaction, or rather the want of reaction, in his cell, was in favor of the view that it is a degenerating cell, and not, as he (Dr. Drysdale) seemed to think, an immature cell; because in immature, rapidly growing cell substances, protoplasms of embryonic character, there existed a special proneness to take on the action of staining and other agents. Concerning the question of diagnosis, he had some time ago reached the conclusion that the cell had no practical value—at least for himself.

Dr. Engelmann, of St. Louis, thought that the ovarian corpuscle was not unlike the syphilitic corpuscle in practical value and destination.

The discussion was closed by Dr. Drysdale, who said that he had quoted from the latest observations made by Carpenter, Max Schultze, and others, as to what constitutes a cell. As to regarding the body as a nucleus, he would have done so twenty years ago, but continued study had convinced him that it was a cell—an aborted,

epithelial cell. The fact that other gentlemen had not seen it, was no fault of his; and he himself had made serious mistakes concerning it, when he had not given fluids a sufficiently careful examination.

AFTERNOON SESSION.

"The Mechanical Therapeutics of Versions and Flexions of the Uterus," was the title of a paper by Dr. E. Van de Warker, of Syracuse.

Do pessaries accomplish what they are designed for? was the question Dr. Van de Warker asked, and its consideration from a purely mechanical standpoint constituted the basis of his paper. His opinion was that the uncertainty in the results obtained by the use of pessaries came (1) from expecting too much of the instrument, and (2) from selecting an imperfect agent for want of more clear ideas of the absolute limitations imposed upon the action of pessaries, and which must govern the mechanical results to be expected. Two things must be clearly defined: 1, the limits imposed by the uterus and its appendages upon the mechanical agencies acting upon it, and, 2, the action of the mechanical forces under these limitations. These limits, both in their mechanical and uterine relations, were fixed and absolute, and were not to be evaded by skill or ingenuity, and ought to be clearly understood. One was, however, reluctantly forced to conclude that the majority of pessaries were invented either in ignorance or defiance of these limits, and as if the only restriction upon their action was that of gravity.

The paper was illustrated by tracings made with the mercurial manometer, showing the movements of the uterus in respiration, forced respiration, coughing, speaking, walking, etc., and was also illustrated with wood-cuts.

The retiring President then made a few appropriate remarks, after which he introduced the President-elect, Dr. Gilman Kimball, of Lowell, Mass., who thanked the Society for the unexpected honor it had so generously conferred upon him.

After votes of thanks to the retiring officers, and to the gentlemen who had so cordially entertained the members and invited guests, the Society was declared adjourned, to meet in Philadelphia on the third Tuesday in September, 1883.

The following officers were elected for the ensuing year: *President*—Dr. Gillman Kimball, of Lowell, Mass. *Vice Presidents*—Dr. A. H. Smith, of Philadelphia, and Dr. Theophilus Parvin, of Indianapolis. *Council*—Drs. Byrne, of Brooklyn; Howard, of Baltimore; Jackson, of Chicago, and Campbell, of Augusta, Ga. *Secretary*—Dr. Frank P. Foster, of New York. *Treasurer*—Dr. Paul F. Mundé, of New York. *Active Members*—Dr. Matthew D. Mann, of Buffalo, N. Y., and Dr. W. H. Baker, of Boston. *Honorary Members*—Mr. Lawson Tait and Mr. J. Knowsley Thornton, of England.

The following papers were read by title: "A New Operation for Ruptured Perineum," by Dr. J. C. Warren, of Boston; "Measurements of the Uterine Cavity in Childbed," by Dr. W. L. Richardson, of Boston.

Canada Medical Association.

The fifteenth annual meeting of the Canada Medical Association was held in Toronto, Sept. 6th, 7th, and 8th; Dr. Fenwick presided. Dr. Graham, of Toronto, read the Address on Medicine. He considered that, from a medical point of view, the two most remarkable events of the past year were the "International Medical Congress," and Koch's experiments on Tubercle Bacilli. He strongly supports Koch's views.

Dr. W. B. Carpenter, the great English Physiologist, was elected an honorary member, and delivered an address on "Vital Statistics."

In the Medical Section, Dr. Osler, of Montreal, read a paper, "Echinococcus Disease in America." The disease seems to be uncommon in America. He could only find reported 9 cases in Canada, and 52 in the United States. It is very common in Iceland, where fully one-sixth of the dogs suffer from it. The ova are introduced into the system, chiefly by means of drinking water which has become contaminated with the excreta of dogs suffering from the disease. The treatment adopted in Iceland and Australia is either tapping or incision. Sometimes the disease is cured spontaneously, either by the bursting of the cyst and discharge of its contents through the bowels or lungs, or by the hardening of the walls of the cyst and the consequent death of its inhabitants.

In the evening Dr. Fenwick read an address, sketching the history of the Canada Medical Association.

Dr. Cameron read a paper on "Axis traction," in which he strongly recommended the use of the axis-traction forceps of Tarnier, which combine the advantages of the straight and double-curved forceps, without their disadvantages. The instrument is powerful and gives a firm grasp to the head, while the axis of the traction handle corresponds with the axis of the blades, so that the line of traction can always be in the line of pelvic axis, without pressing back or injuring the perineum.

Dr. Alloway read a paper on the "Treatment of Abortion." He considers the tampon inefficient, ergot injurious, the finger insufficient, and the placental forceps dangerous. To prevent septic poisoning, he always used a uterine scoop, of his own invention, which he exhibited.

Dr. Rodger, Montreal, said that while he disapproved of undue multiplicity and complication of instruments, he felt that the valuable assistance rendered by them should not be overlooked. He did not approve of the placental scoop which had been exhibited, and considered it dangerous and altogether unnecessary. He spoke in favor of the tampon and placental forceps in the treatment of abortion, and held that improper application of the tampon accounted for its frequent failure.

In the Surgical Section,

Dr. Roddick, Montreal, exhibited a patient who had suffered for many months from a very painful spasmodic contraction of the muscles of one side of the neck. The man was obliged to hold his head between his hands constantly. Dr. Roddick divided the muscles, but with only temporary effect; he then applied the actual cautery frequently to the back of the neck, with most sat-

isfactory result, as the man is now perfectly well.

Dr. Major, Montreal, read a paper on "Rest and Tracheotomy." He urged the importance of rest in all cases of disease of the larynx and throat, and condemned the use of gargles. He called attention to some points in the early diagnosis of laryngeal cancer, heretofore unnoticed, and suggested the use of gold instead of silver or any other metal or material for the tubes. As far as he knew, he was the first to recommend its use.

THURSDAY, SEPT. 7TH.

Dr. Shepherd, Montreal, read the Address on Surgery. After sketching recent progress, he took up the question of club-foot, and discussed the advisability of the early division of the tendo-achillis. Personally, he believes that this tendon should be spared until it had been found that the division of the other tendons was not sufficient to effect a reduction of the deformity.

Dr. Roddick, of Montreal, has not been favorably impressed with dry dressings. He has found moist antiseptic dressings superior to the dry in major operations, where drainage is necessary. He also believes in dividing the tendo-achillis at once, and rarely finds it necessary to divide any of the other tendons.

Dr. Workman, of Toronto, referred to a reported case of the successful use of whisky dressing.

Dr. Ferguson, Toronto, made a statement as to the strength of spray used by Dr. Keith in his later ovariotomies. He had employed a spray of 1 to 30, or even stronger, instead of 1 to 60 as recommended by Lister for cases of ovariotomy. Had he adhered to the weaker spray he would probably not have had evil results from it.

Dr. Stewart, Brucefield, mentioned that a well-known surgeon was obliged to give up the use of spray, on account of its invariably causing him to suffer from hæmaturia.

Dr. Tye, Thamesville, read the report on "Therapeutics." He referred to the dangers of hasty generalizations in therapeutics as well as surgery. The power of medicine is to increase or diminish the functions of tissues or organs, not to change the character of those functions. He dwelt on the use of electricity in anæsthesia, asthenia and suppressed menstruation, and described the effects of the different currents, the magneto-electric, galvanic and frictional, in the treatment of different diseases. The therapeutical effects of some newly-introduced drugs were considered, nitro-glycerine among others. He remarked that, although a large number of new pharmaceutical preparations had been introduced, it was questionable whether some of them were not more advantageous to the manufacturer than the patient.

Dr. Harrison, of Seekirk, read a paper on "A Peculiar Form of Fever," which was sometimes remittent, subsiding occasionally for a few days, and then commencing again. Quinine had no effect, neither did any other form of treatment. Dr. Riddell, of Toronto, thought this was a kind of malarial fever, peculiar to Canada, partaking of the characters of cerebro-spinal meningitis.

Dr. Stewart Brucefield read a paper on "Three Cases of Sciatica and One of Painful Stump, Treated by Stretching the Sciatic Nerve." In some cases, where the operation proved fatal, death was distinctly attributable to the use of chloroform. Ether should always be administered in these cases instead of chloroform. The statistics of the operation are very favorable; 97 per cent. of all cases so treated are either entirely cured or else greatly relieved.

Dr. Prevost, Ottawa, read a paper on "Tumor of Bones of Skull Pressing on Brain." There was an aperture in the frontal bone. The skin covering the tumor was of normal color. The patient's intellect did not appear to be much affected, but he seemed drowsy and dull. He walked slowly, and his memory was impaired. After entering hospital he gradually fell into a state of indifference, which was followed by coma and death. The autopsy showed that the tumor originated in the bone. He exhibited the specimen.

Dr. Cameron, Toronto, exhibited a boy who was being treated for pseudo-hypertrophic muscular paralysis. The treatment consisted of cod-liver oil, syr. fer. iodid., arsenic and galvanism. The boy showed the peculiarity of his movements in going up stairs, and in rising off his back.

Dr. H. P. Wright, Ottawa, read a paper on "Phantom Pregnancy." In the case reported the tumor was situated on the left side, and developed in such a way as to produce in the mind of the patient the idea of pregnancy. The movements of the tumor closely resembled those of a living fœtus in utero. Chloroform was administered and the tumor disappeared, and the patient is now quite well, able to attend to her ordinary duties. Such cases are found chiefly among women subject to undue exertion, spinal irritability and menstrual irregularities.

Dr. Ellis described the chemical composition of milk of cows fed on distillery refuse. He had made an analysis of the milk of cows fed on different kinds of food. The mean of the solids in the milk of distillery cows he had found to be 14.64; of other cows 12.82. The amount of fat in distillery cows' milk is greater than in others, the minimum of the former being equal to the average of the latter. The caseine, sugar and ash ingredients are much the same in both. The principal difference is in the greater amount of fat in the milk of distillery cows. The distillery refuse, on examination, was found to consist of grain with the saccharine matter removed. The fat and albumen remained, together with a small quantity of alcohol, as small as distillers can make it. He could not say whether this food produced any morbid condition in the cows.

In the Surgical Section, Dr. Fulton, Toronto, read a paper on "Polypoid Fibroma of the Bladder in a Child." He says that cystotomy is the only rational method of treating these growths, though a small double-eyed catheter might be used in the case of small growths.

Dr. Ferguson, Toronto, reported three cases of eczema successfully treated with *viola tricolor* internally, and quinine baths locally.

Dr. Goodwillie, of New York, in the course of a paper on "A New Operation for Closure of Harelip and the Hard Palate, immediately after Birth," said that he operated immediately

at birth, and closed the cleft of the hard palate by forcing together the side bones of the mouth, saving all the hard and soft tissues, thus restoring the natural appearance. The nose, which is turned to one side, is straightened and the hare-lip closed. When the operation is completed, the external appearance of the nose, lip and mouth is natural.

Dr. Fenwick, of Montreal, in a paper on "Excision of the Knee," stated that out of 26 cases, 22 recovered with useful limbs, and in only two cases was subsequent amputation necessary.

SEPTEMBER 8TH.

The last day's session was occupied with the discussion of sanitary matters.

ELECTION OF OFFICERS.

The nominating Committe brought in a report recommending the election of the following officers for the ensuing year:—

President—Dr. Mullen, Hamilton.

Vice-Presidents: for Ontario, Dr. Tye, Chatham; for Quebec, Dr. Gibson, Cowansville; for New Brunswick, Dr. Atherton, Fredericton; for Nova Scotia, Dr. Jennings, Halifax; for Manitoba, Dr. Kerr, Winnipeg.

General Secretary—Dr. Osler, Montreal.

Treasurer—Dr. Robillard, of Montreal.

Next place of meeting, Kingston.

Association of Medical Officers of American Institutions for Idiotic and Feeble-minded Persons.

The seventh annual session was held at the Pennsylvania Institution for Feeble-minded Children, Elwyn, Penna., commencing Tuesday, October 3, 1882, at 8 P. M., and continued for three days.

The following papers were presented and discussed:—

1. The "Mathematical Idiot," by Dr. Geo. Brown, Barre, Mass.

2. "Cerebral Localization, Chiefly with Reference to Idiocy," by Dr. C. K. Mills, Philadelphia, Penna.

3. "The Practicability of Instructing Feeble-minded Children in the Various Industries," by Dr. John A. Stewart, Frankfort, Ky.

4. "The Relation of the State to its Charities," by Dr. H. M. Greene, Lawrence, Kan.

5. "Account of a Visit to the Four English Asylums—Earlswood, Darenth, Normans-fels, Lancaster," by Mrs. C. W. Brown, Barre, Mass.

6. "The Organization and Methods of Institutions for Idiots," etc., by Dr. H. B. Wilbur, Syracuse, N. Y.

7. "The Medical Treatment of Idiots and Imbeciles," by Dr. Wm. B. Fish, Elwyn, Pa.

8. "A Few Points in Embryology," with photo-micrograph illustrations, by Prof. W. Hailes, Jr., Albany, N. Y.

The following reports were also made:—

"The Protection of Institutions against Accidental Fire," by Dr. C. S. Wilbur.

"On Bibliography of Idiocy," etc., Dr. H. B. Wilbur, chairman.

"On Statistical Records," Dr. G. A. Doren, chairman.

"On Causation of Idiocy," etc. Superintendents reporting illustrations from cases received into institution for past year.

"Clinical or Historical Reports of Special Cases."

The meeting passed off with great satisfaction to the members present. On the opening evening a reception was tendered the Association, by the board of Directors of the Pennsylvania Institution, which was largely attended, and the guests were hospitably entertained by the superintendent, Dr. Isaac N. Kerlin. An inspection of the Institution impressed all present with its admirable management and the excellent results obtained by the system of education there employed.

Saratoga Waters.

The extraordinary richness of Saratoga and its vicinity in natural mineral waters, is an interesting geological fact and an important one medically. The variety is so great that some one can be found of use in almost any chronic diseased condition. What is singular, exploration reveals waters of constantly diversified character. One of the most efficient of all, the Hathorn spring, was discovered as late as 1868. It is a saline, alkaline water, of very positive therapeutic action, something like the old Congress water, but more efficient. It is believed to contain some lithia, and the reports of its action by medical observers entitle it to rank high among our native medicinal beverages.

Peculiarities of Disease in Egypt.

The *Lancet*, in commenting upon the peculiarities of diseases noticed in Egypt by Baron Larrey during Napoleon's campaigns, 1798–1801, says: Another interesting observation of Larrey's is the occurrence of atrophy of the testicles in many of the soldiers of the army of Egypt, in the year 1799, who noticed, after their return to France, a gradual, painless wasting of these glands, accompanied, when both glands were involved, by the loss of all sexual desire and power. This occurred quite apart from any previous venereal disease. In most cases only one testicle was affected. This atrophy was accompanied by other signs of disease—wasting and debility of the lower limbs, failure of digestive power, discoloration of the face, thinning of the beard, and intellectual derangement. Larrey attributes the atrophy to the effects of great heat combined with fatigue and privations, and especially to the use of eau de vie, prepared from dates, to which the fruits of Solanaceæ were added. When the atrophy was only commencing it might be prevented by vapor baths, dry frictions, stomachics, and good food.

In regard to syphilis, he states that he found the disease to be mild and very easily cured in Egypt, but all forms of inunction were harmful; and if patients returned to France with the disease still uncured it became very intractable.

He observed, with interest, that although dogs abounded in the Egyptian cities, there was no hydrophobia among them. Camels, however, suffered from a form of madness during the time of

rut, and bites from them in this state were dangerous, but the disease was not contagious. The symptoms were the escape of an abundant thick saliva, constant bellowing, horror of water, wasting, fever, falling of the hair, and bad temper, which showed itself by their pursuing men and other animals. If excited, the symptoms increased, and often ended fatally. Horses were subject to ophthalmia, like the men, but this could be prevented by shutting up the stables during the cold, damp nights.

Naval Museum of Hygiene.

The Bureau of Medicine and Surgery, United States Navy, is about to establish a naval Museum of Hygiene. The plan proposed comprehends a collection that shall be illustrative of the entire range of sanitary science, the establishment of a course of lectures by authoritative sanitarians from all sections of the country, and a library of sanitary science accessible, under proper restrictions and guarantees, to all who are engaged in the study of this branch of knowledge. This library already numbers many of the standard sanitary works in the English, French and German languages, and is constantly increasing. It is an admirable undertaking, and we doubt not will be heartily welcomed by both the staff and the profession at large.

Dress Reform.

We note, from the *Lancet*, that the sum of $750 is offered to the Rational Dress Society, to defray the expenses of an Exhibition of Rational Dress, to be held in London during the coming winter. A Prize of $150 will be given for the dress which best accords with the following requirements: 1. Freedom of movement. 2. Absence of pressure over any part of the body. 3. No more weight than is necessary for warmth, and both weight and warmth evenly distributed. 4. Beauty and grace combined with comfort and convenience. 5. Not departing too conspicuously from women's ordinary dress.

Lectures on Dermatology.

Dr. Bulkley will give a sixth course of lectures on diseases of the skin, in the Pathological amphitheatre of the New York Hospital, 7 West 15th street, Wednesday afternoons, from 2.30 to 3.30 o'clock, commencing Wednesday, October 11th, 1882. The course will consist of twenty-four lectures, and will be free to practitioners of medicine and medical students.

Prize Question.

The College of Physicians of this city offers the sum of Twenty-five dollars, or a gold medal, to be awarded at the first meeting in April, for the best pathological report, with or without specimens, read before April 1st, 1883, by any member of the Society who, at the time of presentation, shall hold the position of Resident in a hospital.

Items.

—Dr. Lauderer reports a case in which a woman poisoned a boy, fifteen years of age, by introducing matches into his rectum. He died in great agony the same night.

—The verdict of the coroner's jury at Tunbridge Wells, on the death of a child, was: "The child was suffocated, but there is no evidence to show that the suffocation was before or after death."

—At an inquest held by Mr. Carter, East Surrey, on a man, aged 40, who had been found dead in a loft in Newington, the jury found "That the deceased died from natural decay, caused by his own negligence."

—A physician falls into a fit while making a round of visits, and is carried into a drug store.

"Send for Dr. X——," says somebody.

"No, no, not for him," says the dying man feebly, at the mention of his rival's name; "if he brought me around it would advertise him! I prefer to die."

—Dr. Septimus Gibbon, the Medical Officer of Health for the Holborn district (England) in his recently published annual report, draws distinct attention to the loss of infantile life due to constitutional syphilis. Dr. Gibbon says that this "is a leprosy which entails far worse consequences on the public health than all other preventable diseases put together."

OBITUARY NOTICES.

DR. J. S. SMITH.

Dr. J. S. Smith died at South Solon, Ohio, Monday, August 21, aged 31 years and 6 months. Dr. Smith was born in Washington Co., Pennsylvania, Feb. 10, 1851. In 1874, he was married to Miss Hannah Connett, a young lady of highly respectable parentage. He studied at the Ohio Medical College, Cincinnati, and graduated in 1877. In a short time he removed to South Solon, Madison Co., O., where he had an extensive practice.

SURGEON GEORGE P. JAQUETTE, U. S. A.

Surgeon George P. Jaquette, United States Army, with the rank of major, died recently, in New York, of aneurism of the aorta. Surgeon Jaquette was born in New Jersey and appointed Assistant Surgeon in the army, from that State, on October 23, 1861. He was promoted to the rank of captain in the Medical Department on July 28, 1866, and to that of surgeon, with rank of major, on May 14, 1880. He had been ill nearly a year.

MARRIAGES.

HESTERLY—SCOTT.—In Shreveport, La., at the residence of the bride's father, Dr. J. J. Scott, Wednesday, September 20th, 1882, by Rev. W. C. Dunlap, Dr. F. P. Hesterly, of Fulton, Arkansas, and Miss Lena R. Scott, of Shreveport, La.

WATERWORTH—BOONE.—At the home of the bride's father, Mr. J. Boone, Salem, O., September 13th, 1882, by Rev. H. B. Fry, Dr. William Waterworth, of Brooklyn, N. Y., and Miss Mary Boone, of the former place.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., **PHILADELPHIA.**

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

Lecture.

AFFECTIONS OF THE EXTERNAL OCULAR MUSCLES IN GENERAL DISEASE.

A lecture delivered at the Jefferson Medical College, Spring Course, 1882.

BY WM. S. LITTLE, A.M., M.D.

Reported by Dr. Geo. F. Souwers.

Gentlemen:—I desire in this lecture to present for your consideration the effect of general disease, as it is possible to manifest itself in the impaired action of the external ocular muscles, and exhibits itself principally by producing the symptom of diplopia, or double vision; excluding, however, the condition of convergent and divergent strabismus, due to the state of the eye itself, and involving optical defects, as a primary cause; in such cases double vision is rarely complained of.

The subject is a difficult one, but yet interesting, and of practical value in treating disease. The study of Helmholtz' Physiological Optics is conducive to mental training, irrespective of what practical value it has in helping us in medical practice.

To fully appreciate the abnormal action of the organ of vision and its addenda, it is not only necessary to know the anatomy of the tissues of the eye, but also the optical anatomy of an emmetropic pair of eyes, as they are exercised in performing the act of binocular single vision.

In the visual act it is primarily and imperatively necessary that the fovea centralis of each eye should be directed to or receive impressions from the same object in space at the same time, in order to see singly.

At the fovea centralis the rods and cones of the retina are most exposed to the action of rays of light. The curve of the cornea and the curves of the crystalline lens bend the rays of light, which are parallel before they are acted upon by these structures, so that in an emmetropic eye a burning point or focus is made at the fovea centralis; a space on the retina irregularly oblong and $\frac{1}{4200}$ square inch in size. The location of the fovea centralis decides the position of the visual axis; elsewhere on the retina the focalization of rays of light by the dioptric system of the eye is not so effective, nor is the sense of sight so acute.

The sense of sight is most acute at the fovea centralis, as the sense of touch is at the tips of the fingers; elsewhere on the retina, sense of sight is like the sense of touch elsewhere than at the tips of the fingers; the more remote the less appreciation of the sense.

The external muscles of the two eyes must then act upon the eyeballs, suspended, as each one is, in the orbit, in such a way and with so much force as shall turn the fovea of each eye to the same point or object in space at the same moment of time, to give the mental impression of one image; if the muscles of either eye fail to do this, identical points, or rods and cones in the retina of each eye are not stimulated by pictures of identical spots or points in space, and diplopia or double vision results.

You must remember that the nasal half of the left retina is associated with the temporal half of the right retina, and the nasal half of the right retina with the temporal half of the left retina, while the superior half of each retina cor-

respond, and the lower half of each retina act together. When these identical spots in each retina are not controlled together beyond the point which give us stereoscopic vision, or sense of depth, objects contemplated which should, under control of the muscular sense, appear as one, are recognized as two, and they assume a position either one above the other, both along side of one another, or obliquely placed, according to which muscle has failed to act properly, and their separation depends on the amount of impairment of the muscle; the muscle may be either weakened, paralyzed, or undergoing spasm. The image displaced is called the false image and corresponds to the eye affected.

The sense of two images is perceived as we can produce the sensation of two objects through the touch, by crossing our fingers on one hand in feeling one object, instead of feeling the same object with our fingers in their normal position.

Your knowledge of the anatomy and physiology of the cerebro-spinal system and the nerves distributed to the eye, as well as to all the other organs of the body, enables you to know their normal function. Your clinical observation has afforded you full opportunities to observe how pathological changes in the cerebro-spinal system, as well as nerves going to the various organs, modify the action of separate organs, and you are aware of the influence of diseased conditions in the organs themselves, and their influence on the whole system.

The possibility of impairment of the action of the external ocular muscles, in rotating each eye, by changes in the cerebro-spinal system, or nerves going to the muscles, is easily understood, and by recognizing how a person sees objects in space, you are not only able to tell what muscle of the eye is affected, and what nerve is involved, but often are able to give a more exact location of the primary cause in a lesion present in the cerebro-spinal system itself.

Prof. Ferrier, in his experiments on the cerebral hemispheres by electrical irritation, has produced disturbances not only in the movements of the eye, but nearly all parts of the body. See Chap. VIII, "Functions of the Brain."

Diplopia becomes, then, a symptom of disturbance of the action of the external ocular muscles. The retina of each eye affords visual control over a definite extent in space; in binocular single vision, the definite fields of vision for each eye overlap each other to a definite extent also, and in this space formed by the overlapping of a certain portion of the fields of each eye, single vision for both eyes at once is obtained. This binocular field is called the horopter; to the outer side of this space we see double; and yet this does not annoy us, but is rather a source of protection. For while binocular single vision controls objects in front of us, we have a monocular single field to the right side, and also one to the left, and are able thus to see objects about us to a great extent, as in the act of walking is found necessary. If the limits and extent of the space which should physiologically overlap are not constant and fixed, or under control, a displacement occurs, and diplopia or double vision is produced; an abnormal horopter exists.

You must learn, then, to map out in front of you or your patients the normal horopter, and any abnormal horopter is soon recognized by both yourself and the patient; diplopia is an objective symptom as well as a subjective one.

A normal horopter gives no diplopia, an abnormal one produces double vision, and from the relative position of the falsely projected image to the true, you draw your conclusions as to which eye, muscle, or nerve, or what portion of the cerebro-spinal system, is at fault.

As three different nerves control the six external ocular muscles of each eye, and the nerves arise in the brain on the side of the eye they control, you have in the accomplishment of binocular single vision the associated action of two sides of the brain; six nerves, twelve muscles and two eyes. The act of vision, then, is not unlike the attempt to drive a three-handed team with each hand; only, instead of one wagon to be conveyed, two are being pulled, and they must be kept in a given road without interference. The eyes are the wagons, the muscles the horses, the nerves the reins, and each side of the brain a hand; one rein controls one horse, a second rein another horse, while a third rein controls the remaining four for each side.

For a practical test, a candle held before you, or a blackboard divided into spaces by horizontal and vertical lines several inches apart, taking a vertical line on the board corresponding with the middle of the face and a horizontal line cutting the cornea at the middle; where these lines cut, is a point of fixation; holding the head still, you see where, in the different spaces on the blackboard, a piece of chalk appears single or double. A perimeter is an instrument to make the observation more exact, and affords a record to be made with minuteness. The candle to be held at several, the blackboard two or three feet

from the patient, and the perimeter at the same distance or nearer.

Double vision existing, and desiring to know which eye is at fault, by calling in another sense to help you, namely, touch, you soon clear the diagnosis. Covering each eye separately, and allowing the patient to attempt to touch an object quickly with the hand, the eye at fault prevents an accurate aim, and he misses the object. Then the rotary movement of both eyes in following the describing of a circle in front of the patient, affords a means of diagnosis by a peculiar jerking movement of the eye affected. according to which muscle is at fault. Observe the movement in a pair of healthy eyes and you will soon learn to recognize any deviation. Double images assume two positions in relation to each other, either the object for the right eye is on the right side, and that for the left eye on the left side, or the object for the right eye appears on the left side, and the object for the left eye on the right side; the former condition produces homonymous images, and the latter crossed images, or diplopia. This is readily ascertained by covering an eye quickly and see which image disappears; the right eye being covered, the right image is lost, it is homonymous; the left eye being covered, the right image is lost, it is crossed, diplopia. A red glass over one eye colors one image red, and you thus learn where it is located.

In paralysis of the external rectus of either eye, in paralysis of superior oblique and inferior oblique, the images are homonymous.

In paralysis of the internal, superior and inferior rectus, the images are crossed.

Double vision appears in different portions of the visual field, according to which muscle is affected, and the relative position of one image to the other varies in the same way, and they vary in different portions of the field.

In paralysis of the external rectus of the left eye, and internal rectus of the right eye, images are only double to the left side of a vertical line, in front of the patient; in paralysis of the right external rectus and left internal rectus they are only double to the right of this vertical median line. The images in either of the above cases are parallel in the middle of the field, and diverge at the top and bottom, in the upper and lower portion of the field.

Paralysis of the superior rectus of either eye gives double vision in the upper half of the field of vision; for the left eye objects are higher toward the left side, and obliquity increases to the right; for the right eye the reverse obtains.

Paralysis of the inferior rectus gives double vision in the lower half of the visual field, for the right eye the images more divergent to the left, and less oblique toward the right; the reverse exists for the left eye.

The superior oblique being paralyzed, the images are double in lower half of the visual field; difference in height and obliquity is most marked; for the left eye the vertical separation is greatest to the right, and obliquity to the left. Paralysis of the inferior oblique, which is rare, gives the opposite of the superior oblique. The diagrams before you illustrate all the conditions in paralysis of the various muscles when one muscle alone is affected; when more than one muscle is paralyzed the conditions are more complicated, but are readily diagnosed.

The false image appears nearer than the true one, or on a different plane from the true image.

By displacing one of your own eyes, by pressure of your finger upon the eyeball, corresponding to the location of the different muscles, you can observe all these conditions yourself; or using a prism, and placing it before the eye and looking with both, the same can be seen; the prism must be rotated before the eye, so as to have an effect upon all the muscles in turn.

By means of a prism placed before one eye, we can get an idea or rather an expression of the power of an ocular muscle.

A prism before one eye, the other also being used, gives double images; if the muscle corresponding to the position of the prism is able to unite these images, then place a prism of a greater degree and find a prism that prevents the union of these images. A prism weaker, that allows the fusion of the images, expresses the power of the muscle, just as the degree of the prism that unites images in a case when a muscle is paralyzed, gives the amount of the paralysis.

The muscles in their normal state overcome prisms, as follows:—

Internal rectus prism,	20° to 30°	base	out.
External "	6° to 8°	"	in.
Superior "	1°	"	below.
Inferior "	1°	"	above.
Sup. oblique (my case),	8°	base	obliquely bel.
In. " "	5°	"	above.

You should know the length of the muscles, their weight, size, point of origin, course and place of fixation on the eyeball. For a more extended description of the manner in which binocular single vision is accomplished, you should study for yourselves, in works on Diseases of the Eye, and works on Physiological Optics.

The subject deserves far more than I have presented at this time, and we must now proceed to consider the subject of diplopia being a symptom in general disease, or in what diseases we may find diplopia as one of the symptoms.

Ocular symptoms of general diseases are of the most help in making a differential diagnosis; not unfrequently they are the only symptoms of a diathesis, or symptom of disease in another organ, and their recognition at other times is more evidence added to the other already existing.

Prof. Förster, of Breslau, in "*Handbuch der Gesammten Augenheilkunde.*" Sieberter Band erste hâlfte, cap XIII, has presented the ocular symptoms in general disease and diseases of the other organs of the body, to whose classification may be added the Diseases of Old Age (Charcot). In this present course of lectures, I have been taking up each tissue of the eye, with its addendæ, and giving the conditions as exhibited by the tissue or part of the eye, as produced by the diseases occurring in each system of general medicine, and we will apply the same method in studying the affections of the external ocular muscles, as a symptom of general disease.

Clinically, you will find that diseases of the orbit are the most productive of impairment of the action of these muscles; next affections of the spine and cerebral diseases the least frequent cause of diplopia.

The muscles, as the result of the various diseases, may be simply impaired in their action, or palsied, partially or completely paralyzed, or undergo spasm.

In diseases of the circulatory and respiratory systems, extravasation of blood into the orbit from diseased conditions of the walls of the vessels, or laceration of them from blows or penetration of foreign bodies into the orbit, affect the muscles in their action.

Fractures of the walls of the orbit may allow entrance of air into the orbit, and thus have an effect upon the muscles.

The orbital cavity connects, through foramina, with all the cavities of the head.

In Basedow's disease, while diplopia rarely occurs, the eyeballs protrude, either from weakening of the muscles, or condition of the vessels, or deposit of fat in the orbit.

The orbit, should only contain so much, and any increase or decrease of its contents, irrespective of the eyeball, which, strictly speaking, is anterior to the contents of the orbit, modifies the action of the muscles in a space either encroached upon or restricted.

In diseases of the digestive system, severe constipation has been stated to produce an affection of the ocular muscles. A case is quoted where five or six times this happened to the same patient, a different muscle being affected each time.

No affections of the ocular muscles external to the eyeball are known to occur in diseases of the genito-urinary or reproductive organs of the male or female; certain portions of the eye do suffer through reflex irritation of these organs, however; masturbation and disease of the apparatus may produce asthenopic symptoms.

In diseases of the nervous system, a wide field is open to investigation, and diplopia occurs frequently, along with other more numerous symptoms of disease of the cerebro-spinal system, including the changes in the nerves going to the ocular muscles, and disease involving them in parts lying along their course to the eye.

Simple hyperæmia of the meninges of the brain or spinal cord, or nerves themselves; effusions into the arachnoid space around the nerves as well as changes in the nerve tissue itself, are sources of trouble and impair the action of the external ocular muscles. Periosteal changes also lead to pressure upon the nervous tissue, and modify the action of the muscles. In peripheral irritation following blows on the head or region of the spine, the symptom of diplopia is generally late in asserting itself. Any lesion at the base of the brain, and in and about the fourth ventricle, may give rise to diplopia. Gummata, tumors, aneurisms, tubercle, exostoses, are the most productive causes.

Small growths and lesions apparently insignificant in size, rather than gross lesions, are most likely to affect the ocular muscles or nerves going to them; statistics are as yet too small and observations not definite enough to be of great worth in this line of cases.

In tabes dorsalis, Prof. Charcot has found, in 203 cases, 30 cases presenting affections of the ocular muscles, and this symptom appeared early in the case.

In diseases of the skin, epithelioma, or malignant disease of the skin of the lids, may not only destroy the eyeball, but also the contents of the orbit may become involved; beyond this I know of no associated disease of the muscles from this system.

Rheumatism and gout being classified separately, the tendons of the ocular muscles are involved, as tendons of muscles elsewhere in the body suffer, and while diplopia does not exist, the act of rotating the eyeballs is painful, and their action is modified.

In acute and infectious diseases from changes in the nervous system diplopia occurs; typhus fever, diphtheria, scarlet fever. The condition of strabismus, so often attributed to measles and whooping cough, is to be attributed to optical defects; the convergent squint to hypermetropia, and the divergent to myopia. There are exceptions to this, however, its reverse occurring, and while the disease present may hasten the development of squint, it would have appeared later, irrespective of any disease.

In trichinosis the disease may develop in the ocular muscles, as elsewhere in the tissues of the body.

In constitutional diseases and diseases of malnutrition it is a more common symptom. Syphilis, in its varied forms of development, is the principal cause of diplopia, and gummata developing in the orbit and cranial cavity, and affecting the nervous structure itself, modify the normal action of the parts adjacent, by pressure.

Diabetes allows either a partial or complete paralysis of the ocular muscles.

After typhoid fever, malarial fever, or any cause that lowers the tone of the system, these muscles suffer with the whole body.

In old age lesions in the body that in youth might not have any effect on these muscles, allow an influence to be felt.

From the above, you see, quite a number of diseases have their effects upon the external muscular apparatus of the eye, and its presence should be recognized, not as a symptom of disease of an organ of special sense, but one belonging to general disease, and of value in helping to make a diagnosis.

A few words as to treatment: when diplopia is present, the methods of treatment for combating the disease which has produced the diplopia will relieve the diplopia, along with the other symptoms, and as it improves it becomes important as a factor in making a prognosis. To prevent accidents by misjudging the relation of objects in space and the true direction of things in front, it is better to have the eye at fault covered; so only the true image is observed. If this is not desirable, a prism before the affected eye, with its base toward the image desired to be brought into position, is advisable; as the condition improves weaken the degree of the prism, till, finally, none is necessary; or, in a case of total paralysis, to be worn constantly. Electricity is valuable. Operative procedure should only be undertaken late, not till you are confident no improvement can be attained by the other plans; and even then results by advancement of the opposite muscle merely give a cosmetic effect, and diplopia in other portions of the field may exist. If blindness co-exists with the diplopia in an eye, operative measures are not to be thought of.

Communications.

EXANTHEMATOUS NECROSIS OF THE SUPERIOR MAXILLA.

BY JOHN S. SMITH, D.D S.,
Of Lancaster, Pa.

John S., a boy, aged four years, of the sanguine lymphatic temperament, strumous diathesis, residing in the country, was brought by his mother to my office, in July, 1881, at the suggestion of Mrs. Mary A. Wilson, M.D., and Dr. John L. Atlee, Sr., consulting surgeon of Mrs. Wilson, to have the oral cavity examined. When we first saw him, he presented a pitiable sight. He limped into my presence, the left leg being about one-half inch shorter than the other, caused by an ulcer in the popliteal space. Another ulcer opened on the left side of the thorax, below the clavicle, and one on the left arm near the insertion of the deltoid muscle. The left side of the face was swollen. The body was so emaciated that little hope was entertained of his life.

History of the Case.—In the early autumn of 1880 the child had an attack of bilious remittent fever. Other members of the family were similarly afflicted, one of whom, a cousin, died. About one week after convalescence the child complained of severe pain in his left upper jaw and face, for the relief of which the usual domestic face treatment, hot poultices, was resorted to. The face soon became swollen, and suppuration ensued; an abscess formed, pointing externally. This finally opened near the infra-orbital foramen, discharging large quantities of offensive pus. Subsequently, a number of the deciduous teeth upon that side of the face loosened; these the boy removed with his fingers. Later, a large portion of the maxillary bone and process came away with the remaining deciduous teeth, together with the crowns of the undeveloped bicuspids.

The patient had received no medical treatment from the time he had the fever, in the fall of 1880, till within a month of the time he visited me, in July, 1881, when he came under medical treatment.

Diagnosis.—The foregoing history of the case is sufficient to establish the diagnosis to be ne-

crosis of the maxilla, the extent of which, however, would not be so plain without an examination of the oral cavity.

An examination revealed the parts to be inflamed. The floor of the antrum had come away with the detached sequestrum.

Fortunately, the floor of the orbit (a large portion of which is made up by a process, the orbital, which is part of the superior maxilla), the roof of the antral sinus, was not disturbed.

The left permanent incisor, and the cusp of the canine and first permanent molar, were found loosely imbedded in the stroma. A sinus could be traced with a delicate probe, from within, upward and outward, to a fistula under the rim of the orbit, through the palpebral muscle.

The lower eyelid was drawn downward and turned outward, exposing the inner aspect of the lid, causing an unsightly appearance.

There was some conjunctivitis. The lachrymal flow was profuse. The secretions kept up the irritation to the parts below the eye. The jaw had sustained no external injury. The teeth removed with the sequestrum showed two superficial cavities. The pulp was not exposed. We excluded pulpitis, pericementitis, dental and alveolar necrosis, as a definite signification of the lesion.

In accordance with the clinical history, we class the case with exanthematous necrosis, as the result of the exanthemata. It occasionally, though fortunately quite unfrequently, happens, says Prof. James E. Garretson, "that a subacute inflammation of the jaw occurs, resulting in limited, or, it may be, in extensive necrosis of the part affected." Dr. G., in his clinical and private practice, has met with quite a number of cases.

To Sir James A. Salter, of Guy's Hospital, is accorded the credit of having first directed attention to this form of disease, as far as the recognition of its associations is concerned. The child's age, being under five years, would exclude ostitis as a primary expression connected *with dentition*, whether first or second.

Local Treatment.—The patient was etherized, and the remaining sequestrum removed with the forceps, and the parts thoroughly cleansed. The undeveloped central incisor, canine and first permanent molar, held in the soft stroma, were only acting as irritants, thus keeping up the inflammatory condition of the parts; it was thought best to remove them also.

Pus was almost constantly flowing, either through the sinus under the eye, or being taken into the stomach. A suitable probe was now carried through the fistula, making better vent for the pus outwardly. The sinus was now thoroughly washed with tepid water, throwing it through with a syringe. The subsequent local treatment was stimulating and antiseptic. The parts were ordered to be cleansed frequently by syringing the sinus, thus getting away the offensive, semiputrid pus, in place of allowing it, as before, to pass into the stomach.

The following wash was ordered, to meet the requirements of the case:—

℞.	Tinctura capsici,	f℥ ss	
	Tinctura myrrhæ,	f℥ ij	
	Potassæ permang.,	℥j	
	Aquæ destillatæ,	Oj.	M.

Sig.—Syringe the parts frequently.

General Treatment.—The constitutional treatment consisted in the exhibition of the iodides; of these the iodide of potassium and the syrupus ferri iodidi were given for at least a month prior to receiving local treatment. The treatment was continued for several months after the sequestrum was removed. The patient was advised to take frequent exercise in the open air, and to be given good, nourishing food. In six months he made a good recovery, and was dismissed cured. All that remains to be accomplished in the case is a small plastic operation upon the eyelid; this will be attended to at a future time.

FOREIGN BODIES IN THE POSTERIOR SECTION OF THE GLOBE.

BY M. LANDESBERG, M.D.,
Of Philadelphia.

Cases in which a foreign body, after having penetrated the walls of the globe, has remained for years in the posterior segment of the eye, without causing inflammation and subsequent loss of vision, are of very rare occurrence. Of these instances only thirteen are recorded in the whole medical literature. This tolerance to foreign bodies in its interior, with preservation of good, respectively normal sight, has its counterpart in the tolerance of the brain to the presence of foreign bodies in its tissue, with preservation of normal mental functions. But as in the latter instance the rest may be temporary only and reaction may set in at any time, so may the normal condition of the eye in the interior of which a foreign body is imbedded be disturbed at any time by the outbreak of an inflammatory process, which may not only cause the total loss of vision in the injured eye, but may also involve the other eye in the morbid process, endangering its vision by sympathetic ophthalmia. Should such cases have the only

merit of their being so rare, they would deserve publication every time they happen. But having such an important bearing upon the practice, I need no excuse for drawing the attention of the profession to the following three cases, which have come into my notice during my practice.

CASE I.—CHIP OF STEEL IMBEDDED IN THE POSTERIOR SECTION OF THE GLOBE, WITH RETENTION OF GOOD SIGHT, DURING AN OBSERVATION OF ELEVEN YEARS.

Mechanic, C., 31 years old, presented himself, January 3d, 1870, seventeen hours after a small piece of red-hot iron had struck his right eye. Examination showed: Superficial erosion of the lower lid, near the outer commissure. Several eyelashes are scorched. The conjunctiva of the eye ball highly congested. The outer part of the sclera, embracing just the triangle which is formed by the opened lids, exceedingly chemotic; cornea normal; anterior chamber clear; iris hyperæmic; pupil contracted; upper ciliary region sensitive to the touch; tension normal. On atropia, pupil dilates but slowly, and hardly in the medium. Lens intact; optic disc slightly opaque, highly congested, and of indistinct limits. Somewhat below the lower border of the optic disc, outward from the inferior branch of the retinal vessels, there is an irregularly-shaped whitish exudation, which, rising somewhat above the level of the retina, immerges into the latter without distinct limits. In the centre of the exudation there is a foreign body of bluish lustre and of oblong shape. It is lodged in the tissue of the retina with one end, while the other point projects into the vitreous humor. The latter is of reddish hue, and shows a small, bunch-like opacity, which starts in the form of a stalk, from the locality from where the foreign body projects into the vitreous humor. Inward from the exudation there are several small ecchymoses. V = $\frac{15}{100}$, Jaeger 8. The objects appear somewhat reddish. Field of vision cannot be distinctly measured.

In spite of absolute rest in a darkened room and the appropriate treatment, the reactive symptoms were very intense, and the danger of panophthalmitis imminent. Vision decreased to counting fingers at 8′. But improvement set in from the fifth day and recovery progressed very favorably. On the eighteenth day after the injury the eyeball showed but very slight inflammation. Iris was slightly hyperæmic, pupil medium dilated and without adhesions. Vitreous humor contained only a few filiform opacities. Optic disc hyperæmic, slightly suffused, and of indistinct limits, showed on its inner border a flat extravasation. The exudation was somewhat flatter and smaller, and of gray color. It was surrounded by small masses of darkish pigment. Inward from the exudation there were several flat ecchymoses in the stage of resorption. The foreign body lay flat, embedded in the exudation, representing a darkish line of about two millimeters in length. There were some choroidal atrophies and patches of pigment in the upper outer periphery of the retina. V = $\frac{15}{50}$, Jaeger 3. Field of vision normal. No scotoma.

At the time of the discharge, in the first days of March, the condition was as follows:—

No symptoms of irritation whatever. Vitreous humor contains only a few filiform flakes. Optic disc slightly hyperæmic, of distinct limits. Instead of the exudation we observe in the retina an oblong, grayish streak, in which the foreign body lies embedded. The borders of the streaks and the adjacent parts of the retina are occupied by pigment cells. The ecchymoses have almost resorbed. V. = $\frac{15}{40}$, Jaeger 2. An irregularly shaped scotoma appears occasionally, on dazzling light, in the upper inner quadrant of the field of vision.

Examination, repeated July, 1871, after patient had borne, without the least inconvenience to his eye, all the fatigues of the German-French war, showed V. almost $\frac{15}{30}$. In the background of the eye patches of pigment and the oblong, dirty-gray streak, through which the foreign body could be seen, but on favorable illumination only, as a dark line.

I saw patient again, by chance, June, 1881, after I had lost sight of him for ten years. The eye had remained healthy all the time. V. was $\frac{20}{30}$. The dirty gray streak was totally covered by small clusters of pigment, which left no trace of the foreign body.

CASE II.—SPLINTER OF IRON IMBEDDED IN THE RETINA, BETWEEN OPTIC DISC AND MACULA-LUTEA, WITH RETENTION OF NORMAL SIGHT DURING AN OBSERVATION OF FIVE YEARS.

Mechanic, S, 35 years old, came to me June 5th, 1877, two hours after a chip of iron had struck his left eye. There was moderate subconjunctival injection, slight photophobia and lachrymation. The cornea presented, on its outer border, just on the horizontal meridian, a small penetrating wound, and opposite the latter there was, in the stroma of the blue iris, a linear dark streak of about 2 mm. in length. Anterior chamber was clear, pupil somewhat contracted. Background of the eye could not be distinctly seen. V = $\frac{15}{20}$, Jaeger 1. Field of vision normal.

Impressed with the idea that the dark streak in the stroma of the iris might indicate the place in which the foreign body had lodged, I abstained from instillations of atropia, in order to avoid any dislocation of the foreign body by the contraction of the pupil, and resorted at once to iridectomy. But no foreign body could be found in the removed piece of iris. The healing process was normal. Examination, made June 13th, after the pupil had been dilated to the utmost, showed lens perfectly clear. Some filiform flakes in the vitreous humor, and on the retina, between optic disc and macula lutea, a circumscribed, whitish exudation, through which a dark, pointed body, of oblong shape, could be distinctly seen. The outer border of the exudation, near the macula lutea, contained some small blood extravasations. There was but slight retinal hyperæmia. V. $\frac{15}{50}$. Outward from the point of fixation there was a small scotoma, of oval shape.

Under appropriate treatment the symptoms of irritation vanished rapidly, vitreous humor cleared up entirely and exudation resorbed. The place was marked by the appearance of small nests of star-shaped pigment cells, which, rapidly proliferating, collected into small clusters, which lay close to each other. Finally, all line of demarkation vanished, and we had before us a small conical hill of pigment, under which the foreign body was buried. August 4th, patient was discharged with V. $\frac{15}{20}$, and with normal field of vision. This condition remained unchanged during the five years of further observation.

CASE III.—SPONTANEOUS ELIMINATION OF A SPLINTER OF BRASS FROM THE INTERIOR OF THE EYEBALL, FOLLOWED BY RESTITUTION OF NORMAL VISION.

Mechanic, M., 25 years old, came to me, April 26th, 1881, with the following condition of his left eye: Slight lachrymation and photophobia. Intense peri-corneal injection, and considerable venous hyperæmia of the mucous membrane of the eyeball, which is especially pronounced in the segment bordered by the opened eyelids. In this part there is also serous infiltration. The outer border of the cornea, just opposite the insertion of the external muscle, shows an irregular, small scar, and beneath the latter there is a small, jagged loss of substance in the iris. The latter is hyperæmic, and of greenish color. Pupil dilates only slightly to atropia, and displays multiple filiform adhesions to the lens capsule. The latter is occupied by punctiform exudations. Vitreous humor is hazy. Background of the eye cannot be seen. Tension is slightly diminished, and the upper ciliary region sensitive to the touch. V. = $\frac{5}{200}$, Jaeger 18. The space between the insertion of the external muscle and the sclero-corneal border is occupied by a deep ulceration, having the form of a crater, the edges of which are hard, prominent and infiltrated. Through the layer of pus which covers the bottom of the ulcer, a glittering body, of the size of a pin's head, can be seen, which feels hard when probed. After the bottom of the ulcer had been cautiously cleansed, there could be distinctly recognized, best by means of a magnifying glass, a glittering three-pronged point of a foreign body, the whole of which was lodged in the interior of the eyeball. I succeeded to grasp the point with forceps, and to extract the whole body, which presented itself *as a fine, oblong splinter of brass*, of 2½ mm. in length.

Anamnesis revealed that, on February 13th, a chip of the piece of brass patient was just shaping on the lathe had struck his left eye, causing, immediately, intense pain, which kept on for hours. A physician, to whom patient applied at once, could not find the foreign body. The consequent inflammation was combated by all possible antiphlogistic measures, to which was added, in the third week, an attempt to remove a piece of iris, which is indicated by the jagged loss of substance in the iris, as referred above. But all these procedures failed to give any relief. Vision sank rapidly. April 20th, patient first noticed the appearance of an ulcer near the outer border of the cornea.

Compressive bandage, applied on both eyes, brought about quick and smooth closure of the wound. Irritation subsided entirely. After iridectomy vision increased to $\frac{15}{70}$. Vitreous humor cleared up, so as to allow ophthalmoscopic examination. There was equatorial choroiditis, whitish plaques, and disseminated clusters of pigment in the retina.

A mercury treatment, combined with the internal use of the fluid extract of jaborandi, brought vision to $\frac{15}{30}$. Vitreous humor clearedup almost entirely, and the whitish plaques disappeared.

—The *Boston Med. and Surg. Jour.* says: The necrology of both Harvard and Yale Colleges this year is of interest as showing the tendency to longevity amongst educated men. Of the 78 dead in the Yale list for the year, 31 were seventy years of age or over, the average being over seventy eight. Of the 71 dead in the Harvard list, 29 were over seventy, the average being over seventy-seven years. In each list the extreme age reached was ninety-six.

Hospital Reports.

HOSPITAL COLLEGE OF MEDICINE, LOUISVILLE, KY.

CLINICAL LECTURE, BY DUDLEY S. REYNOLDS, M.D.

Professor of Ophthalmology and Otology.

Stenographically Reported for The Medical and Surgical Reporter.

Otitis Media Purulenta.

Inflammation of the middle ear is a disease confined to no particular class of people, to no rank or station in life, although it would appear to be limited, in its geographical distribution, to those sections known as malarial. Tuberculous subjects, syphilitic subjects and habitual smokers are particularly subject to different forms of inflammation of the middle ear, the nature of the process being dependent always upon the cause. The catarrhal and the blenorrhœal may be generally though not always readily distinguished one from the other, as well as from other forms. It may perhaps be well to include the parasitic, which results from the invasion of the morbid process from without inward, through a perforated drum membrane, though it is not my purpose to consider in detail at present all the varieties alluded to.

It may be laid down as a rule in practice, that all discharges of pus from the external ear come from the tympanic cavity, through the perforated drum membrane. There are, however, a few exceptions to this rule, yet, if the rule be recognized and the practitioner proceed accordingly, the safety of the patient will be secured as far as medical skill may be relied upon. No one but the skilled aural surgeon may be able to determine the difference between those forms of otitis discharging pus externally from abscesses forming in the course of the external auditory canal, and those more common forms, the discharge from which originates in the cavity of the tympanum. If, however, the Eustachian catheter be employed with sufficient care in those cases where Valsalva's method of inflation is impracticable, the current of air may often be forced into the cavity of the tympanum, blowing out all the morbid contents through the perforated drum membrane, or where no perforation exists, by the counter current of air down by the side of the catheter, through the Eustachian tube into the fauces. The first point to be considered is the location of the morbid matter, whether it be pus, muco pus, or bloody serum. Otitis media is a very common form of catarrhal inflammation, extending by continuity of structure through the walls of the Eustachian tube from the pharynx to the tympanum, and it very rarely occurs in persons who are not already affected by the constitutional manifestations of malarial poisoning.

It is therefore important to supplement the local by constitutional treatment.

To illustrate these points, I have before you M. O'C., aged 9 years. She is well nourished, and has been apparently in good health until day before yesterday, when she appeared stupid at school; was kept in for not knowing her lessons, and when she returned home at 4 o'clock, complained of headache, and suffered from fever during the night. Yesterday morning she had a cough, was hoarse, and suffered from obstruction of the nose; last night she was seized with violent pain in the right ear, which has continued unabated to the present moment. She has been subjected to the application of hot flaxseed poultices to the ear and the whole side of the head. These I just a moment ago removed, and now examination shows a reddish yellow tint, and bulging of the drum membrane, the external auditory canal being entirely free from any kind of morbid material. Puncturing the posterior and inferior quadrant of the drum membrane allows a quantity of straw-colored serum to escape, and the child refusing to try Valsalva's method of inflation, I pass a Ginsoul catheter through the nostril into the faucial orifice of the Eustachian tube, and apply the nozzle of a Politzer's air-bag to the distal end of it, gentle compression being followed by a gurgling sound and the escape into the external ear of about half a fluid drachm of bloody serum and some shreds of lymph. (From the moment of puncture the pain abated, and as soon as the morbid matters were blown out of the cavity of the tympanum the child expressed herself as entirely relieved.)

She shall now be ordered to take five grains each of calomel and chlorate of potash in one powder, and ten grains of quinine as soon as this shall have operated upon the bowels. She is to report to-morrow morning, and I am confident, from past experience in such cases, that she will have no more pain, and that the trouble will by that time be so far recovered from as to allow closure of the puncture in the drum membrane, the accumulating fluids making their exit through the Eustachian tube into the pharynx.

Annie D., aged 7 years, has had a discharge from the left ear since infancy. The disease in her case came on much after the manner detailed in the case just before you. The family physician, after the drum membrane ruptured and the matter began to escape externally, said it would not be safe to arrest the discharge, lest the disease might go to the brain and prove fatal. His advice was accordingly taken. Two weeks ago, to-day, the child was brought here with a very offensive discharge from the ear and almost complete loss of hearing. Examination revealed depression of the drum membrane of the right ear and an absence of the inferior half of it in the left. The nose was occluded with pus; the posterior wall of the pharynx, as seen through the mouth, appeared glazed and intensely red.

The child had been under the treatment of a great many physicians, and, of course, a great variety of therapeutic measures had been tried. You may remember the astonishment expressed by her mother when, two weeks ago, to-day, with the aid of an atomizer and a solution of chloride of sodium, five grains to the ounce of water, the nasal passages were cleared. The naso-pharyngeal space was in like manner cleared, and the introduction of the Eustachian catheter first into the left side resulted in the blowing out of the ear a large quantity of tough mucus, a quantity of pus, and afterwards a little bloody serum.

The odor was horribly offensive, and I introduced about two drops of listerine into the distal end of the catheter, and applying the Politzer air bag, forced it through the middle ear into the external canal. The bad odor was almost instantly overcome. The catheter was next applied to the right side, and the drum membrane easily forced into its proper position, a flapping, tearing sound, following each compression of the bag, was produced by the escape along the side of the catheter, into the pharynx, of the tough mucus which is generally present in chronic moist inflammations of mucous membranes.

The child's hearing was almost instantly restored to a degree permitting conversation to be heard. I have practiced the introduction of the catheter into the left Eustachian tube, and the application, as already detailed, of the listerine, almost daily, and now to day, before I begin the treatment, you observe she hears my watch with the right ear at the distance of eight inches. The amount of discharge from the left ear is so slight that no overflow has occurred to-day. The mother informs us that the child's ear was washed out with a syringe and salt water, as usual, early this morning, after which two or three drops of listerine were instilled. There is at present but a faintly perceptible odor accompanying the discharge. The pus is no longer present in the nose or pharynx.

The only treatment for the nasal and pharyngeal affection, aside from the use of the atomizer, with the chloride of sodium, followed by a dilute preparation of listerine—one part to three of water—has been the occasional snuffing of the powdered borate of soda.

Miss W., æt. 24, has had a discharge from the right ear since infancy. She had a polypus in the left ear, which filled up the whole canal, and extruded nearly half an inch beyond the tragus. She said this had been removed a great many times by different surgeons, but it always returned. One month ago to-day, you may remember, I injected it with a 60 gr. solution of chromic acid. A week afterwards there remained only a small portion of the stump, which was again likewise injected.

The whole mass of morbid tissue disappeared. The right ear was catheterized from time to time, and listerine blown through the catheter, in order to insure its contact with the walls of the tympanum. The drum membrane has been partly renewed in the right ear, and almost wholly so in the left, the polypus having sprung from the petrous portion of the temporal bone, near the point of union between the drum membrane and the wall of the auditory canal. There is now but a very slight discharge from each ear, no offensive odor, and the patient is able to hear all ordinary conversational tones. You may remember, when she first came to the clinic she was almost entirely deaf, and stated that she could not hear it thunder, though she could see it.

Mr. H., æt. 23 years, lives in Charleston, Indiana; came two months ago with an offensive discharge from both ears, unable to hear the loudest tones distinctly enough to conduct a conversation. I present him to you to-day, with a small perforation in each drum membrane, no discharge whatever, and, as you perceive, able to engage in ordinary conversation. He hears my watch, which should be heard at thirty-six inches, four inches from the right ear, and by slight contact with the pinna of the left. Mr. H. has been treated regularly twice a week, as most of you know, by the introduction of the Eustachian catheter, first blowing out all morbid materials from the tympanum, and then the introduction of one drop of the listerine, which was blown through the tympanic cavity. He has used powdered white sugar and tannic acid, in the proportion of a drachm of the acid to the ounce of sugar, as a snuff, twice every day.

His pharynx, which was filled with purulent accumulations, now presents very nearly a normal appearance, and his voice is clear, whereas before it was muffled. I may mention that he has taken iodide of potassium, beginning with ten grains every four hours, and increasing by the addition of five grains to the dose every ten days, until he now takes thirty grains. There is no history of syphilis, and he presents none of the characteristic phenomena. The iodide of potassium was suggested by the engorged state of his lymphatic glands. His tonsils, which were larger than almonds, are now invisible. Thus you see Mr. H. has been relieved of what, for years, rendered him odious to his friends in a double sense. The odium of being too deaf to engage in conversation, has disappeared, as the odor which offended the nostrils of his companions has likewise passed away.

Unable to go more fully into the subject, I feel that, from the cases before you, two important points as to local treatment, or rather as to the action of local agents, should be mentioned more particularly. First; there is in such cases the necessity for an agent which has the power to dissolve the fibrinous matters upon the surface of the inflamed mucous membrane, and immediately following this, an agent which has gently stimulating, astringent and antiseptic powers. The first agent, as you have seen, is found in the chloride of sodium, the second in listerine. Listerine is something more than a mere antiseptic, which its inventor, Mr. Lambert, has very extensively advertised as its chief virtue. It is a stimulating, balsamic astringent. It contains boracic acid, the essential oil of eucalyptus globulus, thymol and some other less important ingredients. It mixes freely with water, and may be used as a local application to all purulently inflamed surfaces, diluted to any extent desirable, or as in the cases before you, in full strength. With chloride of sodium and listerine, you have, therefore, but little to desire in the way of local applications in otitis media purulenta.

Medical Societies.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, October 5th, 1882. Vice-president, T. M. Drysdale, M.D., in the chair.

Dr. W. Goodell exhibited the specimens, and gave the histories of the following cases.

Renal Cyst.

Mrs. C. M. G., aged 52, and married for twenty-eight years, has had three children, the youngest of whom is twenty-five years old. For many years she has had pain in the left renal region, and sharp attacks of gravel. This pain was so increased by jolting, that she was unable to drive, even in a carriage with double springs; but she has never experienced the excruciating pain of a stone passing down the ureter; of this she is positive. Four years ago she began to enlarge, but she did not suspect a tumor. As her health grew worse, she came on from the west, and in last July consulted Dr. J. F. Bird about it. He recognized a cyst, and called Dr. Goodell in to see her. Despite her age, her catamenia were not only regular, but too free. Dr. G. expected to find a fibroid, but the womb measured only three inches, and it was also very movable and wholly independent of a large cyst which filled up the abdomen like an eight months' fœtus. The lower edge of the cyst could be felt per vaginam, lying in front of the womb. Percussion elicited all the phenomena peculiar to ovarian cysts. Coronal resonance was marked. There was dullness in front, showing the complete absence of intestines from that region, their presence being alleged to be one of the most trustworthy signs of a renal cyst. As the lady stated positively that there were changes in the size of the tumor, Dr. G. was disposed to regard it more as a cyst of the broad ligament, than one of the ovary.

The operation was performed on September 16th. As soon as the cyst was reached it was ascertained that it was not ovarian or parovarian; but it was fully fifteen minutes before its true character was discovered. The cyst was covered with a very vascular but loose layer of peritoneum, to which, in the lateral regions, the intestines were attached and in which they seemed to be imbedded. This was cut open and stripped off from the whole cyst, which now revealed, on its lower border, an expanded and healthy portion of the left kidney. To confirm the diagnosis, a small calculus was found within the cyst and a much distended ureter discovered. The pedicle formed by this process of enucleation consisted, below the ligature with which it was secured, of the renal blood-vessels enveloped in connective tissue. But to get a button of tissue sufficient to prevent all slipping of the ligature, the operator was obliged to leave on its distal side a small portion of the cyst, but none of healthy kidney.

It was evidently a case of hydronephrosis, but the uterine sound was passed into the ureter and no obstacle was met with; it probably did not reach the bladder. This ureter was brought out at the lower angle of the wound and secured there by one of the sutures. Nineteen days have now elapsed since the operation, and the lady has done uniformly well, and sat up to-day, for the first time.

Hydatid of Morgagni,

The lady from whom this specimen was taken was operated on by Dr. Goodell, on September 4th, and promptly recovered. The cyst was of the left ovary, but the right one, being also diseased, was also removed. Attached to one of the fimbriæ of the oviduct is a very beautiful specimen of a hydatid of Morgagni. This little body, so often found attached to the ovary, was of interest, because those small cysts of the abdomen which, after obtaining a small size, would burst and usually refill, were, in Dr. Goodell's opinion, cysts of this hydatid.

Cyst of the Parovarium.

This specimen was taken from a young woman, aged 22. The tumor was first noticed eight years ago. Dr. Goodell aspirated her before the clinic at the University of Pennsylvania, in October, 1880, and November, 1881. On each occasion a perfectly limpid fluid was removed, and the diagnosis was consequently made of cyst of the broad ligament. As the cyst again refilled, she demanded its removal, and she was accordingly operated on before a ward-class, on September 19th. The cyst sprang from the left side, and had the usual delicate and vascular wall. Spread out on its lower border is the corresponding ovary, which could be very readily overlooked by a careless observer. The right ovary being much enlarged, and filled with small cysts, was also extirpated. When first removed, it contained a fine corpus luteum, but the alcohol had dissolved this out, leaving merely the deep pit which held it. The operation was performed just two weeks after her last monthly period. The usual metrostaxis occurred on the fifth day after the operation. The patient is convalescing well.

Papillomatous Uterine Growths.

Dr. W. H. Parish exhibited two vials containing apparently similar growths, removed from the endometri of two patients, one of which, from concurrent symptoms, he considered benign, but the other he thought malignant. In the first case menstruation had ceased for a year, after which it had returned and become constant and profuse. She had suffered from prolapse, following labor, twelve or fifteen years ago. Dr. Parish dilated the uterus with two sets of sponge tents, after which he introduced his finger and found a number of elevations as large as peas; some of these he removed by means of curettes, and others by seizing them with forceps and twisting them off. Some metritis followed the operation, but no blood has been lost in the last four weeks.

The second specimen was removed from a carcinomatous uterus, by means of the curette and the écraseur.

Dr. Goodell remarked that he did not allow the revelations of the microscope to govern him in his treatment of bleeding uteri. He had under his care recently three such cases, all of which were reported by noted microscopists to be carcinomatous, but one of these cases was entirely cured by local measures.

One case of lacerated cervix, with ectropium and free hemorrhage, which was pronounced undoubtedly cancerous by a microscopist of high repute, was relieved by scraping, and cured by operation. Another case, pronounced cylindrical epithelioma by the same gentleman, recovered after operation.

A patient of Dr. C., while in this city, was re-

ferred to me for examination as to the cause of persistent menorrhagia. Ether was given and a careful and thorough examination made, and the round and sharp curettes were used, but Dr. Goodell could find no cause except a few minute granulations. This class of cases is usually found among stout or plethoric women, and the hemorrhage will recur after any treatment, although temporary benefit can be obtained. When the curette is passed over the walls of the uterus it exercises a tonic effect, and a contraction results, checking the hemorrhage

Dr. A. H. Smith has had under treatment a number of cases of marked anteflexion, generally in young girls, in whom dysmenorrhea is followed by very profuse menorrhagia, which proves very exhausting, and will not yield to internal remedies. Examination shows no recognizable cause, but a stem pessary will secure entire relief in a few months. He has seen six such cases within the last three years. He has had under treatment cases resembling epithelioma of the uterus, in which the introduction of a large sponge tent has resulted in complete cure and secured the cessation of profuse and hitherto uncontrollable hemorrhage.

Dr. Parish: Some cases of incurable hemorrhage are due to inflammatory adhesions of the uterus to surrounding tissues, which will disturb the circulation and modify nerve action. He considers the smooth wire curette a valuable aid in diagnosticating the condition of the endometrium as its passage over the uterine wall will distinguish between healthy and unhealthy uterine tissue.

A patient suffering from uterine hemorrhage for three weeks following a possible miscarriage at three months, was cured by one application of the smooth curette, which brought away some granular matter.

Recovery from Traumatic Tetanus.

At a recent meeting of the Cambridge Medical Society, *British Medical Journal*, Mr. Shields related the case of a lad who had recently been treated in the hospital, for tetanus, and recovered. A healthy country lad, aged 17, was admitted on May 30th. He was suffering from an extensive lacerated, contused wound, on the flexor aspect of the left forearm, the result of the explosion of a gun. The superficial muscles were extensively disintegrated; the radial artery was torn away, but the main nerves had escaped injury, and the ulnar artery was intact. The wound was treated by poultices and carbolized oil, and all went well until June 17th, when symptoms of tetanus set in, with slight stiffness about the muscles of the jaws and of the neck. On June 19th these symptoms had become more pronounced; well marked trismus was present, with epigastric pains. By June 23d the disease was fully developed. Severe spasms, especially of the muscles of the back, were constantly present; the tongue was foul, the breath offensive; the bowels were constipated, and the pulse quick; while the temperature was high, and the urine scanty and high colored. Excessive sweating was also present, so that an eczematous condition of the cutaneous surface was produced. From June 23d to July 12th the symptoms were very severe. Marked opisthotonos was observed, and the patient became rather emaciated. On July 10th the disease was on the wane. Gradually the spasms grew less severe; the bowel acted naturally, and the appetite improved, while the patient was walking about the ward, and his wound nearly healed, and all tetanic symptoms were gone. Throughout the whole case, the temperature was, for the most part, above normal—presenting curious diurnal variations. On several occasions it reached the height of 104° and 105°. The pulse was quick and weak, and varied slightly with the temperature. The treatment adopted depended chiefly upon feeding and nursing. Plenty of good milk and eggs, with port wine and brandy, were frequently administered, both by day and night, and fortunately swallowed and retained by the patient. Hypodermic injections of morphia were administered every evening, and caused relief and some snatches of sleep. The bowels were relieved by enemata; and during their peristaltic action the patient seemed to have his sufferings increased; but after the evacuation the pains were alleviated. He smoked tobacco twice, and this gave him some relief from the accumulation of mucus in the fauces. Dr. Humphry believed tetanus to be a passing malady, depending probably, like smallpox, scarlet fever, and others, upon some blood poisoning; like them being amenable to no known treatment, but running a certain course and subsiding, provided it did not kill the patient. Of the rapidly progressing cases, very few survived; whereas in those which came on more tardily, and more particularly in those in which the patient continued to be able to take food, a favorable result might not unfrequently be obtained. The disease was attended with much wasting and exhaustion, sometimes with high temperature; and the most important feature in treatment was to give nourishment, which must generally be in a fluid form, milk, eggs, beef tea, wine, etc., as much as the patient can take. While food could be swallowed, there was hope; and it must be urged upon the patient. Sedatives, such as morphia hypodermically injected, tobacco, etc. come in as adjuncts in more severe cases; but reliance should be placed on the feeding, with attention to the bowels, it being commonly necessary to give aperients. In some cases he had

found tobacco, smoked or administered in a mild form, to have a soothing effect. He had kept patients persistently under the influence of chloroform without any benefit. The maintenance of strength by nourishment, so as to enable the patient to tide over the attack, was the great thing to be aimed at.

Anencephalic Monster.

At the last meeting of the South Carolina Medical Association (*Transactions*) Dr. A. A. Moore related the following case:—

I was called into the country, December 12th, 1880, to attend Mrs. M., in labor, a primipara, aged twenty-four years. She had been in pain all the previous night, and when I arrived at her house, about 10 A. M., the pain was incessant, although it came in occasional paroxysms of increased severity. The pulse was more frequent than natural, but did not indicate exhaustion, and the respiration was normal. As is often the case, there was constant dribbling of the amniotic fluid from the vulva, and yet the distention of the abdomen did not sensibly diminish. It was unnaturally prominent and rotund, so that there was no projection of any of the bony points of the fœtus; and, in consequence of its large size, I began to suspect that I had a case of twin pregnancy to deal with. On vaginal examination, I found the external parts moist, soft, and in a proper condition for an easy delivery. The os uteri was only partially dilated, and what appeared to be the amniotic sac was very tense and unyielding, so that I could not discover even the presentation; I waited two or three hours longer until the os had fully dilated, when I ruptured the sac with my finger, and there was a long and copious gush of water, flooding the bed up to the patient's shoulders, and running down on the floor. Examining again, I recognized the rugged, deformed head of the child presenting. After a few severe throes, a hideous monster was delivered, stillborn, a photograph of which is here presented. The frontal bone down to the superciliary ridges, the whole of both parietal bones, and the occipital bone, except the basilar process, were all wanting. In other words, the whole vault of the cranium was absent, there being no visible trace of a brain. A thin fringe of black hair bordered the flat surface of this imperfect skull. There was also complete absence of the cervical vertebræ, the head being firmly fixed upon the thorax. In addition to this there was a cleft in the spinal column, immediately below the head, forming spina bifida, into which, and down the vertebral canal, I passed a probe its entire length. The child (a female), though small, was perfectly formed in every other respect. I believe that what was apparently a distended amniotic sac, was in reality a very large dropsical effusion of the encephalon, attended by deficiency of the bones, muscles and integuments, and it was this that I ruptured, and that retarded the progress of labor.

The mother of the child is a blonde, very well developed and healthy. On inquiry, I could not trace this deformity to the questionable influence of any maternal impression. The father is twenty-nine years old, of dark complexion, with black hair and eyes. He has been treated for phthisis, I believe, and has been quite dissipated in his habits. Whether his consumptive tendency, or his besotted life, or both, had any agency in the procreation of this unsightly offspring, I will not attempt to discuss.

In the July number, 1867, of the *American Journal of the Medical Sciences*, I reported an almost exactly similar case, except in that instance there was no fissure of the spinal column, and the cervical vertebræ were present and perfectly formed.

Strangulated Hernia in a Woman Aged Eighty-five—Recovery.

Dr. C. A. Owens reports the following case in the *Lancet*:—

On September 23d, 1879, I was called to see M. S., an old woman, aged eighty-five, who was suffering from sickness and constipation. I found that these symptoms had been present for 120 hours, and were due to the presence of a right strangulated femoral hernia. There was a tense, hard, painless tumor in the corresponding region; she had the usual anxious expression of countenance; pulse 75; temperature 101°. The vomiting was not stercoraceous. Having tried the taxis carefully, but without success, I applied an ice bag to the tumor, and tilted up the foot of the bed, which proceeding had enabled me to succeed in reducing a hernia under similar circumstances. Later in the day I again visited the patient, and finding reduction impossible, I administered chloroform to her, with the understanding that if taxis then failed I should proceed to operate without further delay. Taxis not succeeding under chloroform, I operated in the usual way, being obliged to open the sac, and relieving the stricture by slightly nicking Gimbernat's ligament. The bowel was congested, but retained its natural lustre, and was returned into the abdominal cavity without any difficulty. The wound was closed by sutures, and dressed with a pad of lint supported by a spica bandage. The patient rallied well after the operation, and I left her comfortable, with instructions to take an opiate, to procure sleep.

September 24th. Patient cheerful; had rested well without the opiate, which she declined to take, as well as a stimulant in any shape; no pain; temperature 101.5°; pulse 72. 25th. Patient, though uncomplaining, was not quite so well; her temperature had gone up to 103°; pulse 96, and intermittent; no sickness and no tenderness of abdomen. 26th. Patient better; pulse 96; temperature 102°. 27th. Much better; temperature 100°; pulse 112. Bowels had moved naturally without medicine. The patient continued to improve.

October 1st I removed the dressing, and found the wound entirely healed; sutures removed. From this date the patient advanced rapidly to perfect recovery without any untoward symptoms.

Remarks.—This case is worthy of notice, on account of the very advanced age of the patient (eighty-five) and the length of time the hernia was strangulated. No credit can be given to opium, as she took none, either before or after the operation; nor to stimulants, for the same

reason, the patient having a decided aversion to their use. She was out in the fields, gleaning, in three weeks, and is alive and well now, at the advanced age of eighty-eight. I was assisted by my partner, Mr. Barton, during the operation.

Vaso-Constrictor Nerves.

The *Lancet* says that an elaborate study of the sympathetic nerves which cause the dilatation of the vessels of the mouth and lips has been made by MM. Dastre and Morat. Two years ago they announced the discovery, in the cervical trunk of the sympathetic, of filaments, the function of which is to cause dilatation of the vessels of one region of the head, and thus to antagonize the action of the other fibres of the sympathetic. If the spinal cord is divided in the lower part of the neck, stimulation of the posterior segment causes a primary dilatation of the vessels of a large part of the head, especially in the region of the ear and of the mucous membrane and skin of the nose and mouth. The result is the same in the cat, rabbit, hare and dog, and seems to show that vaso-dilator nerves arise from this part of the spinal cord. If the dorsal nerves, from the second to the fifth, are exposed, divided, and the peripheral ends are stimulated, dilatation of vessels occurs, but in a limited region of the mouth and face, and only in the dog. The result only follows stimulation of the anterior roots. Hence, in this animal, at any rate, the vaso-dilator nerves seem to leave the cord by this path. A similar experiment with the branches from these roots to the sympathetic, gives the same result and conclusion, and may, in like manner, be followed up the cervical sympathetic trunk. Many fibres were traced by the experimental method into the fifth nerve. The course of the nerves being thus ascertained, an attempt was made to excite them by an agent less artificial than electricity. Asphyxial blood is a powerful stimulant to the central nervous system, but it stimulates both classes of vascular nerves, and one or the other effect may predominate. In the bucco-facial region the effect of asphyxia is congestion. If the sympathetic is divided on one side, the congestion is much slighter, sometimes is absent. Hence the asphyxial vascular dilatation must be due, in part, at least, to the influence of these sympathetic fibres. A dilator action may also be excited by reflex influences. Stimulation of the central extremity of the divided vagus, isolated from the sympathetic in the lower part of the neck, causes a primary and bilateral dilatation, which is lessened or prevented by preceding division of the sympathetic. It is also prevented if complete muscular relaxation is produced by the inhalation of chloroform, or if the spinal cord has been divided. It is especially considerable if the stimulation is applied to the superior laryngeal nerve, or to the trunk of the vagus, as far as the origin of the pulmonary branches, but is almost absent when the stimulation is below this point. Bucco-facial congestion may also be produced by excitation of the central end of the sciatic or of the tibial nerve, and probably also of other cutaneous branches. A certain degree of congestion is produced by asphyxia, and by reflex excitation, after the division of the sympathetic; and when sufficient time has elapsed to permit the degeneration of the nerve fibres, stimulation of the superior maxillary nerve still causes a certain degree of congestion of the corresponding lip. Hence the cervical sympathetic appears not to contain all the vaso-dilator nerves of this region. In this respect the dilator nerves of the vessels resemble the dilator nerves of the iris, which run in part only in the sympathetic trunk.

On the Bacteria of Typhoid Fever.

The *Medical Times and Gazette* says that Dr. Ernest Almquist, of Stockholm, who had been assiduously occupied for eight months in proving the presence of a bacterium (microbe) in the living blood in typhoid fever, records in the *Nordiskt Medicinskt Arkiv*, 1882 the conclusions at which he, so far, has arrived He made these researches on a considerable number of preparations of normal and pathological blood, before coagulation. After coagulation, formations are found in the blood, which are perfectly similar to bacteria, and are probably formed from torn meshes of fibrine. In the blood of persons suffering from typhoid fever, bacteria are frequently found, but very small and very few. Each bacterium has the appearance of a cylindrical, short and slender rod, the extremities refracting light more powerfully than the middle, which appears more transparent. Still more rarely there are found in typhoid fever other formations—as short protoplasmatic threads, or as ovoid grains. On rare occasions he has detected the presence of an enormous mass of bacteria; but only for one or two days, in the whole course of the fever. It is not certain that a greater number will be found in severe than in abortive cases, for in these latter Dr. Almquist has often discovered a considerable number. The bacteria are found most frequently in the second and third weeks. He thinks it necessary to search for pathogenic bacteria at the bedside of the patient, and then they are found in the blood in the purest possible condition. To obtain certain results, pure seeds must be obtained if it is wished to cultivate them or to inoculate an animal with them. Workers have, he says, too much neglected researches of this kind, and they have sought for the bacteria of a patient in the excretions, in the dead body, and even in the earth itself. In the case of typhoid fever much time and trouble are necessary, in order to find a number of bacteria sufficient to cultivate them so as to make them serve for inoculation; but it is worth the trouble, for the harvest, once found, soon gives results. In many infectious diseases it will be undoubtedly very easy to procure them, and perhaps it will be possible to fix the very day when the bacteria will be most frequently found in these cases. It may be presumed that the pathogenic bacteria can be perfectly cultivated in normal blood, especially in that of a person who has never been attacked by the fever. Dr. Almquist has cultivated this bacterium, taken on the eleventh day from the blood of one of the cases described, in a drop enclosed between two glasses, one of which was concave. From this drop there were prepared successively a series of generations, and

from the second generation he succeeded in inoculating a dog, with good results. The animal was hardly ill, but on the fifteenth day he found the Peyer's patches much swollen, and containing characteristic bacteria. Without having yet finished his researches, Dr. Almquist thinks that he is able to form the following opinions, viz.: The bacterium (*microbe*) of typhoid fever is found in the blood only by accident; it vegetates principally in the walls of the intestine, and only in very small numbers in ordinary cases, and, if more are found, he thinks they are thrombi of bacteria, which, having been detached from their places, circulate in the blood, broken into particles. He then describes six forms of bacteria, which are illustrated by microscopical drawings. He thinks, from his researches, that the microbe he describes cannot strictly be classed among the genera *Bacillus*, *Micrococcus*, or *Bacterium*, but that the series of developments comprises the following phases, viz.: The spore shoots forth a thread; several threads form a network, a mycelium, or a zooglœa of threads. If the spores are completely formed in the threads, then the zooglœa of threads may be transformed into a zooglœa of delicate grains. Dr. Almquist has not yet concluded his researches, to which he intends shortly to return.

Hypodermic Injections of the Atropia Salts.

The principal physiological effects of administration of the salts of atropia are: dryness of the mouth and throat, dilatation of the pupils; in larger doses, difficulty in speaking and swallowing, numbness of feeling in the face, amaurosis, cephalalgia and vertigo, gay or sad delirium; hallucinations, nausea; slowing up and later acceleration of the pulse; scarlatiniform redness of the skin, œdema, etc. When toxic doses are given, besides the symptoms already mentioned, there is aphonia, muscular spasms, collapse, and finally death with arrest of heart in diastole. The toxic phenomena supervene in from two to ten minutes when the drug has been hypodermically injected.

No local accidents are observed after the subcutaneous injection of a solution containing the neutral sulphate or the valerianate of atropia, provided the solution be absolutely pure and contains neither acid nor alcohol. A good solution for hypodermic use is the following:—

℞.	Atropiæ sulphat.,	gr. iss	
	Aquæ destill.,	℥ iij$\frac{1}{3}$.	M.

Twenty drops of this solution contains about one-sixteenth of a grain of atropia. Small doses, not more than one-twentieth of a grain (10 drops), should be used at first, and the dose of one-thirtieth of a grain (40 drops) should be rarely exceeded.

In the following prescriptions, morphine is associated with atropine, and good effects are obtained in combating pain and insomnia. The following is a prescription employed by M. Dujardin-Beaumetz:—

℞.	Morphiæ muriat.,	gr. iss	
	Atropiæ sulphat.,	gr. $\frac{1}{6}$	
	Aquæ lauro-cerasi,	℥ v.	M.

Fifteen drops of this solution contains one-third of a grain of morphine, and one-twentieth of a grain of atropia. The following solution is employed by M. Gueneau de Mussy:—

℞.	Morphiæ muriat.,	gr. viij$\frac{1}{3}$	
	Atropia sulphat.,	gr. $\frac{1}{6}$	
	Aquæ destill.,	℥ iiss.	M.

Fifteen drops, about one gram, of this solution contains one-sixtieth of a grain of atropia and five centigrams, or about one grain of morphine. About four drops will be the proper dose to commence with. This association of atropine with morphine has been recommended by such observers as Brown-Sequard, (1860), Harley, Frankel, Prevost, etc. From a therapeutic point of view, atropia is indicated particularly in neuralgia, asthma, incontinence of urine, constipation, chorea, intestinal occlusion, vaginismus, tetanus, epilepsy, sweating in phthisis, vomiting of pregnancy, etc., but its best effects are obtained in excessive sudation or intense pain.

Medical and Surgical Uses of Belladonna and Atropia.

In the *Lancet*, Dr. J. H. Whelan says:—

Without going deeply into physiology, let me briefly summarize the evidence of cardiac inhibition, its causes, and the effects of atropine.

1. If we send an interrupted current into the exposed vagus of an animal, after an initial latent period (which is .16 of a second in the rabbit, according to Donders), the heart stops beating and remains in diastole.

2. If we give a dose of atropine before applying the electrodes, no such thing takes place.

3. The application of muscarin or pilocarpine seems to produce profound cardiac inhibition, which a small dose of atropine removes.

4. Nicotine paralyzes the cardio-inhibitory vagal fibres, after first stimulating them, while atropine seems to have an effect on the heart itself as well. The results of experiments teach us that the hypodermic injection of atropine before chloroform inhalation may ward off death itself. In some extreme cases of hysteria or allied disorders, we have patients going from one faint into another; frequent syncopic attacks. In the allied abnormal condition of pregnancy, that called by old authors hypothæmia, we have the same condition. In both, this drug ought to prove extremely useful. In the former we have impulses originating probably in the higher centres, causing frequent inhibitions; in the latter the uterus takes the place of the brain. I once saw a very interesting case under Surgeon Hamilton, in the County Meath Infirmary. A man was brought in suffering from slight localized abdominal tenderness and obstinate constipation. The pain increased, and the pulse became very weak and fast, while the constipation continued, in spite of many remedies. He was ordered a grain of extract of belladonna every hour. After the second dose the pulse had improved wonderfully, and assumed the normal type in all characters. He got ultimately worse and died, when a perforating ulcer of the pylorus was found. Leaving diffi-

cult explanations aside, I think we have in the deadly nightshade a means by which we can prevent persons from fainting. By the hypodermic use of atropia the surgeon may remove the effects of the shocks of gigantic wounds of railway accidents and battle. I remember a hysterical girl in whom I at different times opened a minute abscess and removed two dental stumps. By each little operation she was caused to faint several times. Finally, in the last instance, before using the instrument, she was given twenty-five minims of tincture of belladonna, with the result that she did not faint, neither did she manifest any signs of weakness. If, then, as it seems, we are in possession of a drug which will prevent cardiac inhibition, cases of "death from shock" ought to fade from the death register of surgical practice. Belladonna will be found sometimes serviceable in nocturnal emissions, when these are accompanied by erections.

Dr. Gentilhomme, of Reims, has used a pill containing $\frac{1}{100}$ of a grain of sulphate of atropine in coryza, with marvelous results. Fifteen minutes after the first administration all sneezing had ceased, the secretion stopped and respiration became normal.

Reviews and Book Notices

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. V. H. Taliaferro, of Atlanta, Georgia, gives further evidence of the value of systematic pressure in uterine disease, in a reprint of 20 pages, before us. It is well worth the careful perusal of gynecologists. The author will supply copies.

——In a reprint from the *Archives of Ophthalmology*, Dr. Julian J. Chisholm, of Baltimore, narrates two interesting cases, one of cataract extraction with iridectomy, in an infant only six months old, the other of congenital paralysis of the sixth and seventh pairs of cranial nerves, in an adult.

——The Medico-Legal Society of New York has got into a row about publishing its Transactions, and the Treasurer, Dr. E. C. Harwood, has come out in a pamphlet of 32 pages, explaining why he declines to pay the printing bills. Doctors never did get along well with lawyers. Of course, we believe the doctor is in the right.

——The value of a bandage and compress in present or threatened mammary abscess is extolled by Dr. Geo. H. Noble, of Atlanta, in a reprint from the Atlanta *Medical Register*. The measure is undoubtedly a useful one, but it is by no means so new as Dr. Noble seems to think. It is frequently mentioned in German gynecological works.

BOOK NOTICES.

The Treatment of Diseases by the Hypodermatic Method. By Roberts Bartholow, M.A., M.D., etc. Fourth Edition. Philadelphia: J. B. Lippincott & Co., 1882. 1 vol., 12mo, pp. 365. Cloth, price $2.00.

The author, in his preface, makes an appeal in favor of the substitution of the form hypodermatic for the more usual hypodermic. The former has the authority of Aristotle, and is more consonant with the rules of derivation in Greek Grammar. The revision of the text has been thorough, and the additions amount to 114 pages. A careful survey and estimate of all the recent accessions to the literature of this therapeutic method are presented, and probably there is no other monograph on this subject, in any language, which is so complete. The method is one of the greatest value when properly used. By no other means can we produce equally prompt and pleasing results. The hypodermic syringe is now, to the intelligent practitioner, as indispensable a part of his personal equipment as the lancet was fifty years ago.

Fistula, Hemorrhoids, Painful Ulcer, Stricture, Prolapsus, and other Diseases of the Rectum, their Diagnosis and Treatment. By William Allingham, M.D., etc. Fourth revised edition. Philadelphia: P. Blakiston, Son & Co., 1882. 1 vol., 8vo, cloth, pp. 168. Price $1.25; in paper, 75 cents.

This excellent monograph has had a just popularity, and the author has in the present edition availed himself of his more extended experience, to add materially to its value. It is, indeed, probably, the most satisfactory treatise extant in its peculiar field.

On Asthma, its Pathology, and Treatment. By Henry Hyde Salter, M.D., F.R.S., etc. William Wood & Co., New York.

The above is the September number of Wood's "Library of Standard Medical Authors." Dr. Salter's work has not previously been republished in America, although for many years in England it has been a popular monograph. It is, to be sure, not very well "up to the times." Several of the new remedies in asthma which we have looked for in its index are not mentioned. But as a meritorious exposition of the older methods of treatment and pathology it still has solid value.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A PHYSICIAN'S DUTY TO HIS PROFESSION.

"Every professional man," says Lord Bacon, in an oft-quoted passage, "owes a debt to his profession." We say this is an oft-quoted passage, but we doubt if its exact intention is often thought over.

Bacon, no doubt, was reflecting that the professions occupy the honorable positions they do, solely through the labor that has been bestowed upon them by our predecessors in them. The fruit of this labor we inherit on entering a profession; we, therefore, are morally bound to add something to the general mass of learning, which bestows its dignity on our profession.

No one has a right to practice medicine, for example, solely to get a living: not even ought he to do it solely for benevolent purposes, though we know no one who is open to this charge. While it is a business, and is to be treated as such, every physician should feel that duty demands from him that he add something to the general stock of medical knowledge. We can do this in many ways.

With the numerous societies that are now organized, he can always share the best results of his experience with appreciative colleagues. With a medical press as active as ours, if he has any taste for writing, he can always address a large audience through the columns of a journal. In many States, the State Medical Society, or the State Board of Health, are always desirous of information on local diseases and medical climatology, on vital statistics and domestic hygiene.

No matter how remote from the centres of professional labor he may be located, no matter how limited or monotonous may be the circle of his observation, every physician could, if he would, and studied how to do so rightly, add materially to the fund of scientific knowledge.

Suppose such a one was to review all the features of his locality, geological, topographical, meteorological, botanical, hydrographical, and having grouped them properly, endeavor to find out how they affected longevity, the general health, the course of common diseases, the production of uncommon ones, the progress of epidemics, etc. We care not where such a study were made, if judiciously carried out, it would be read with profit by physicians in every part of the world.

Gœthe has said that the secret laws of all vegetable growths are illustrated in the humblest weed. This our profession may say: that within the purview of every one of its members is enough to keep him busy, with profitable study, for life.

Let no one complain, therefore, that he has no chance to find out anything new; that his "opportunities" are too narrow. It is not the opportunities that are at fault, it is the capacity to utilize them.

Professor Virchow said, in one of his lectures, that of ten medical students to whom he would show a pathological specimen, nine could not see it. That is, they could not understand its bearings and significance. He justly deplored this absence of the faculty of observation. But the absence is not irremediable. If a man sets about it with right good will, he can overcome any such deficiency. Inertness, narrowness of view,

routinism, indifference to higher motives, these are the foes of most serious power.

We urge, therefore, those who feel this lethargy creeping upon them to resist it. Especially is it destructive to young men. They should determine not to grow rusty; they should always cherish some purely scientific part of medicine; they should make it a rule to read a new book, and to write an article for a society or journal, every few months. Thus they will avoid the fatal mental dry-rot that attacks so many.

THE ADVANTAGES OF COUNTRY LIFE TO LITERARY MEN.

It is a significant and noteworthy fact that many of the greatest lights of the literary world have resided in the country. It is a universally admitted fact, by those competent to judge, that a residence away from the centres of commercial activity, in other words, a suburban residence, is most conducive to physical health. So, it would seem, is it to the mental health and activity of man. That this should be so, is not to be wondered at, when we remember that it requires a *sound body* to enclose and develop a *sound mind*. But independently of the corellation of physical and mental force, aside from the influence that a healthy body has on mental activity and fertility, there are other reasons why country residence is calculated to be beneficial in an especial manner to the literary worker.

Continuity of thought, in the first place, is very essential to literary progress. If a man desires to accomplish a certain problem in psychical life, it will require a certain time, according to the rapidity with which he is capable of performing mental labor. If a man starts out to walk a given distance, it will require a certain time, according to the ability he possesses for walking. If, now, in either pursuit interruptions occur, the accomplishment of the proposed task will be delayed, just in proportion to the number and duration of these interruptions. In the ever changing panorama of city life, in the almost inevitable and numerous demands upon the time of a resident of a large city, from one source or another, the absence of such interruptions is well nigh impossible.

In the second place, communing with nature and all its wonderful works certainly does have a refining, elevating and purifying influence on the thoughts that may have been suggested by more worldly surroundings.

It is true that the surroundings and necessities of city life bring up to the mind subjects for consideration, but the country is the place in which to elaborate and perfect them.

This idea is carried out by experience.

The country air of Gad's Hill enabled Dickens to perpetuate his wonderful pictures of metropolitan life.

The pure air of small New England villages has enabled our great American poets to sing the songs of beauty that will make their names forever revered; while it was stated at the recent meeting of the British Medical Association, that some of the greatest elements of progress in our profession had been contributed by country doctors; indeed, the very founder of that time-honored institution was himself a provincial physician.

Thus, then, while the crowded city offers peculiar advantages to the commercial spirit, while therein money can be best accumulated, yet the higher type of manhood, the lover of thought, he who ponders that he may by so doing benefit and advance his fellow men, will find the best pasture upon which to browse his noble aspirations in nature's sweet and pure country.

ONE OF THE DIFFICULTIES OF JOURNALISM.

Readers of a journal like ours expect to get all the latest medical news. Whatever may have been detected new in the wide field of medicine, if it is in England, France, Germany, Italy, Russia, or anywhere else, a subscriber to a medical journal expects his to be the first communicating the latest facts. But very few have an idea how many foreign journals have to be read through, and what the difficulties are under which an editor of a medical paper labors. The Russian physicians, for instance, are of late making rapid progress, and we have often already re-

ported interesting cases, directly translating them from Russian journals. But that this is not an easy work, that their language is a very difficult one, we want to give our readers some little idea, by simply mentioning the *titles* of a few Russian medical journals which are at the disposal of the editor of that branch in our paper:—

"Westnik Ssudebnoi Medizini and obsohtschest wennoi Gigieni" (Messenger of forensic Medicine and public hygiene).

"Wratschebnija Wjedomosti" (Medical Paper).

"Lyetopissy Moskooskayo chirurgitscheskago Obtschestwa" (Annals of the Moskau Surgical Society).

"Ieschenrdjelnajaklinitschezkaja Gazetta" (Medical Weekly Gazette).

"Wratsch" (Physician), a journal which has a very large circulation.

"Medizinski Sborink Imperators kawo Kawkas kawo Medizins kawo Obschtschestwo" (Medical Messenger of the Imperial Kankas Medical Society).

DRUG FARMS.

In a recent issue of a prominent English medical journal there appeared a short notice on this subject, which we read with interest.

It is a well known fact that our country is over-stocked with physicians, hence we see so many young, bright, well educated and thoroughly competent doctors struggling and starving, almost, along the narrow, crooked and rugged path that leads to professional success. Some of these gentlemen possess, or at least, can command, some small amount of capital, and land, even near our large cities, somewhat remote from railroads, can be bought at a very low price and on very easy terms. There are many articles in our materia medica that can be raised in the climate of our country in the open air, and many others that could, no doubt, be successfully cultivated in hot houses.

The profit on drugs is very large, so that very little ground, if used at all successfully, would yield a very large revenue.

Would it not be well for some of our young men to turn their intelligence into this channel? Their leisure could be devoted to study, while they might be enabled to make a good living, at least until they had attained that *age* so essential to success in the practice of our profession, if they did not care to permanently engage in such a pursuit.

Notes and Comments.

To Detect Bacillus Tuberculosis, for Diagnosis.

Dr. Heneage Gibbes recommends, in the *Lancet*, the following process, which will bring out the bacillus with ease and certainty, and in his hands has never failed. The colors used are magenta crystals and chrysoidin; the latter is a brown, which does not stain the ground substance so intensely as vesuvin. They can be procured from the Badesche Anilin Fabrik, 22 Bush-lane, Cannon-street, E. C. The following are the formulæ he has used: Two grams of magenta crystals, three grams of pure anilin, twenty cubic centimetres of alcohol, specific gravity, 830, twenty cubic centimeters of distilled water. Dissolve the anilin in the spirit and then rub up the color with it, in a glass mortar, adding the spirit gradually until it is all dissolved; then add the water slowly, while stirring, and keep in a stoppered bottle. Make a saturated solution of chrysoidin in distilled water and add a crystal of thymol to make it keep; a dilute solution of nitric acid (Coml) is made, one part of acid to two of distilled water. For sputum the following process is the most simple. Spread a thin layer on a cover glass and let it dry; when quite dry pass it two or three times through the flame of a small Bunsen burner and let it cool. Filter two or three drops of magenta solution in a watch glass; place the cover glass with the sputum downward on the stain, taking care there are no air bubbles under it. Let it remain for fifteen or twenty minutes, then wash in the dilute acid until all color has disappeared; remove the acid with distilled water, when a faint color will return; then place the cover glass, in the same manner as before, on a few drops of chrysoidin filtered into the bottom of a watch glass, and let it remain a few minutes until it has taken on the brown stain; wash off the superfluous color in distilled water and place the cover glass in absolute alcohol for a few minutes; remove and dry perfectly in the air; place a drop of Canada solution on the cover glass and mount. It is better to use small glass funnels for filtering the stains, as they protect the fingers. Sections of hardened tissue are treated

in the same manner, with the necessary modifications. With regard to the powers required to examine these bacilli after they have been mounted by this process, an ordinary $\frac{1}{4}$ inch with daylight will show them perfectly, and a $\frac{1}{8}$ dry glass will show that they are rows of spherical bodies, with the same illumination. Their diagnostic value remains to be settled.

Therapeutics and Physiology.

Dr. Geo. F. Yeo concludes an address in the *Lancet* on "Experimental Physiology and Practical Medicine," as follows:—

Rational therapeutics must grow out of physiological knowledge, as surely as a plant is the outgrowth of its roots. As the remote rootlets are the exact parts which are all important for the nutrition of the plant, so experiment feeds physiology, and thereby nourishes the art of medical practice. It would appear silly to ask to what rootlet any single fruit or flower on a widely-spreading tree owed its existence or nutrition, and so it is idle to expect that each, or even any, therapeutical agent or method of diagnosis should be traced to the definite experimental discoveries that may have led to its adoption or use. As the branches of our medical tree spread wider and wider, and its diagnostic flowers and therapeutic fruits become more and more numerous, we find that its physiological roots go deeper and deeper, in search of pabulum, and the experimental rootlets become still further removed from the more obviously useful and prolific part of the plant.

A New Remedy for Spasms.

The *Med. Central. Zeit.*, of July 15, 1882, publishes the result of experiments instituted by Dr. Schiffer, of Berlin, for the purpose of determining the therapeutic value of the *extract of Guachamaca*, a tree indigenous on the Apuche mountains. As a specific for all spastic conditions of the motor apparatus we so far possessed, in reality, one remedy only; curare, which, however, on account of its danger, and the uncertainty of its action, as well as of the remedy itself, has mostly been used for physiological experiments alone, and, perhaps, occasionally in tetanus.

Guachamaca extract, prepared from the bark of the Quebracho plant, which belongs to the same class as the Oleänder (Nerium ol. L.) and of which latter the skin between tree and bark is also poisonous, is a remedy which, while not so dangerous in its effects, is far more reliable and uniform in its action, and can besides easily be procured pure and genuine, and of always equal strength, as it is by no means rare.

Schiffer experimented with this drug, and made his observations in the clinic of Prof. Frerichs. He employed the remedy in solution, in the dose of $\frac{1}{8}$ of a grain, and by the hypodermic method, in cases of tonic and clonic spasms of the muscular system, and always with a very good effect. He noted also that, administered internally, no matter in what solution, the drug was as little absorbed by the mucous membrane of the alimentary canal as curare is.

Should further trials with this remedy prove invariably as successful, or at least frequently so, as was the case in Schiffer's experiments, we would at last possess a reliable specific for all spasmodic affections of muscles and motor nerves, a drug, the physiological action of which would be exactly opposite to that of strychnine and similar remedies.

Turpentine for Tænia Solium.

In the *Southern Clinic*, Dr. H. L. Harris relates the case of a mulatto girl to whom he gave on a Thursday afternoon—

℞. Ol. terebinthinæ, ℥ ss
Ol. ricini. ℥ iss. M.

Sig.—Tablespoonful at a dose.

And directed that one dose be taken, and that the patient retire fasting, and await developments until one o'clock Friday.

At 12.20 o'clock. Friday, he was summoned, and found she had passed a monster tapeworm, measuring seventeen and a half feet in length, careful measurement. She suffered from soreness over the hepatic region, but the abdomen has fallen, and the patient feels well.

Tuberculosis of Urinary Apparatus.

Mr. Reginald Harrison reports, in the *Lancet*, a condition of affairs occurring in a patient in the Liverpool Royal Infirmary, to which the term "Urinary Phthisis" has been applied. He had seen a good many instances of it in hospital practice, the patients being usually sent there on the suspicion that they were suffering from stone. The symptoms of urinary tuberculosis so closely resembled those of stone that an examination of the bladder with the sound was unavoidable. Under all circumstances it was necessary that such an examination should be conducted with the greatest gentleness and delicacy. This condition consists essentially in tubercular deposits and ulcerations of the urinary organs, while similar deposits usually exist elsewhere throughout

the body. In connection with the diagnosis, Mr. Harrison directs attention to the great value of careful and continued thermometric observation. In the irritability which accompanies stone in the bladder and tumors, an evening rise in temperature is only met with under very exceptional circumstances, it cannot be said to be symptomatic of these affections; while in urinary tuberculosis it is constantly observed, and is to be regarded as an objective symptom of importance.

Paris Health Report.

At a recent meeting of the Soc. Méd. des Hopitaux (August 11th), M. Ducastel read the report on the reigning diseases for the second quarter of 1882. The mortality is much higher than that for the same quarter for several years past. Typhoid fever and diphtheria have cruelly stricken both the hospital and civil population. Pulmonary diseases have been more common and of greater gravity than usual. In the hospitals 378 cases of diphtheria have been received instead of 267 for the same period last year; in the city outside the hospitals 728 cases were reported, instead of 523 noted last year; the disease was of exceptional gravity, the mortality being as high as 70 per cent. During the month of June typhoid fever was exceedingly prevalent, and during the quarter 452 cases were received in the hospitals; in the city 192 deaths from this disease were reported, instead of 97 for the same period in 1881.

Therapeutics of Tetanus.

Dr. James R. Wallace furnishes, in the *Lancet*, statistics of tetanus in the Medical College Hospital of Calcutta, from which we note that after revising the notes in forty-six of the cases in which recovery took place, he fails to find one in which success can be attributed to any single remedy, or any individual plan of treatment, though in most of them chloral and cannabis indica were more largely used than other drugs. The practice in which surgical operations were performed for the relief of the sufferer has been attended with most unfavorable results. In two cases the sciatic nerve was stretched for tetanus arising from wounds of the foot; in one instance the median was subjected to the same operation, for disease originating in a comminuted fracture of the thumb, and in neither of these cases did abatement of the spasms or other improvement in the patient's condition attend the procedure. Amputation of the hand in two cases, of the forearm in three, and of the leg in two, was resorted to without effect. And he concludes that if any drugs are to be relied on, favor is decidedly on the side of chloral, opium in the form of morphia, and opium smoking.

Multiple Myom of the Neck of the Uterus.

On the anterior lip of the uterus of a woman, 49 years old, a tumor the size of a walnut, and on the posterior lip, one of the same character, of the size of a hazel nut, was detected. The case is reported by Dr. v. Rabenau, in the *Berl. Klin. Wochenschrift*, 1882, *N.* 11, and is especially interesting, as every indication pointed to a malignant growth, and only a trial excision proved the benign nature of these tumors, both being myom. For their radical removal the neck of the uterus was amputated.

Another point of interest in this case, and one which, under similar circumstances, may have not a little weight in deciding the diagnosis, is the fact, that the mother of the patient had been operated on several times, for submucous myomata, which in her case had all been provided with pedicles, and this had made the diagnosis easier. Such cases are, on account of their favorable prognosis, and because they might easily be taken, at the first glance, for malignant tumors, of great importance, a myom possessing sometimes almost the same hardness to the touch as a cancer.

Excision of the Tongue.

Mr. Croly, of Dublin, performs the following operation for cancer of the tongue, even when the disease is situated in the anterior portion of the organ. He first ligatures each lingual artery close to the hyoid bone, through a curved incision, reaching from the symphysis down to the hyoid bone, and up and back to the angle of the jaw. Through these incisions he withdraws the tongue, as in Regnoli's operation, and removes the requisite amount of it by the benzoline cautery. Lastly, he divides the gustatory nerve where it lies along the inner border of the jaw-bone.

Therapeutics of Chloral Hydrate.

In the course of an article on this subject, in the St. Louis *Medical and Surgical Journal*, Dr. Joseph E. Harris recommends chloral for seasickness, 15–20 grains every four hours; for the nausea and vomiting of pregnancy, in inflammations, eruptive fevers, etc., especially when at-

tended by adynamic symptoms; in cholera and cholera morbus, in nearly all nervous disorders, in delirium tremens, in puerperal eclampsia, in infantile convulsions, in tetanus, in whooping cough and spasm of the glottis, and concludes with the statement that hydrate of chloral is a nervous sedative, carminative, hypnotic, an antispasmodic, antiseptic, antiphlogistic, and we may say anæsthetic; but gives the following caution: It should be prescribed with the greatest caution, if at all, when there is ischæmia of the arterial system. It should not be prescribed, for instance, in pneumonitis, in which there is bound to be a great disturbance of the pulmonary circulation.

Stenography for the Blind.

Prof. Arnold, the Director of the Berlin Institute for the Blind, has at last succeeded in teaching stenography to the blind. He presented, in a meeting of savants, held in Berlin during last month, a boy, æt. 13, born blind, who was able to write a lecture down about as fast as an expert writer with the perfect use of his sight can do, when making use of common letters. He then read, just as fluently, what he had written. The lecture was on political subjects, and included a geographical description of Greece; for an expert stenographer with undisturbed vision, even, a rather difficult task. Herewith is, at last, solved a difficult problem. Prof. Arnold mentioned, also, that he found less trouble in teaching the blind this system than the common method of writing, and that especially a great deal of time was saved and a new source of income opened to those unfortunate persons who were born blind.

Rupture of the Uterus.

Dr. Macdonald presented to a recent meeting of the Toronto Medical Society (*Canada Lancet*) a uterus in which rupture had occurred during labor. The woman, a primipara, was unmarried, aged 26, and healthy. The pains were moderate. During the prevalence of a rather severe pain she felt something give way. The pain ceased, moderate hemorrhage occurred, and there was tenderness over uterus. Collapse rapidly set in, hemorrhage profuse. Examination revealed a rent in anterior wall of uterus, through which the hand readily passed into the abdominal cavity. Ether and ergot were given subcutaneously. Delivery was effected by turning. Child dead. The woman rallied somewhat, but died thirty-nine hours after the rupture. A large quantity of fluid extract of ergot and five drachms of ether and brandy were given subcutaneously. The rupture was seven inches long.

Subcutaneous Injections of Iodoform in Syphilis.

Dr. Thomann, of Gratz (*Med. Wiss.*, O t. 1881), has treated several cases of intense syphilis by hypodermic injections of iodoform, and generally after ten or twelve such injections, has obtained a notable amelioration of the symptoms. The preparation he uses consists of six parts of iodoform dissolved in twenty of glycerine; of this from five to twelve drops may be progressively injected. He has never observed an abscess, but slight swelling and pain may occur at the point where the needle penetrates. Iodine is detected in the urine within two hours after the injection, but no odor of iodoform can be found in the respiration, urine, or cutaneous perspiration. Dr. Thomann has also used a solution of iodoform in olive oil, but found it much more irritating than the other.

Ergotin for Prolapsus Ani.

A boy, æt 5., suffered two years from this complaint. After each act of defecation the bowel prolapsed, 5–7 ctm. The treatment instituted was first the usual one: cold effusions, cauterizations with nitrate of silver, the application of the tincture of the chloride of iron, and the internal use of tonics, besides regulation of the diet and attention to the secretions, especially preventing constipation. But the morbid condition continued more or less invariably the same. At last a suppository was made use of, consisting of ergotin, 2 to 3 grains, and of butyrum cacao q. s. The country practitioner who reports this case, in the *Arch. d. Pharm.*, June, 1882, remarks that the effect of this remedy bordered almost on the miraculous; after the application of a few suppositories, the ailment was cured.

Eczema and Vaccination.

Dr. J. Herbert Stowers reports, in the *Lancet*, the case of a child in whom eczema commenced at three months of age, in consequence of which vaccination was postponed. When two years old it was seized with confluent smallpox and only recovered to be permanently afflicted with terrible facial deformity. Five other members of the same family who remained in the house throughout this child's illness were unaffected. They had been successfully vaccinated. He furnishes this case as a warning to physicians not to allow eczema to stand in the way of vaccination.

Atropin for Dribbling from the Mouth.

Dr. G. F. Yeo says, in the *Lancet*, that often, in cases of paralysis, and sometimes in fracture of the skull, dribbling from the mouth is a most distressing symptom; it saturates the pillow and robs the poor patient of much needed sleep. A little atropin injected under the skin in the neighborhood of the gland, checks for hours the flow of saliva and enables the sufferer to enjoy a quiet sleep.

Over-distention of the Stomach.

Dr. Langmann reports, in the New York *Medical Journal*, the case of a man who was troubled with dyspepsia and occasional severe cardialgia, during which time the peristaltic action of the stomach could be plainly seen. The capacity of the stomach was five quarts; the introduction of a tube was invariably accompanied by vomiting. After once washing out the stomach, immediate improvement took place. There are several similar cases recently reported.

Special Reports.

NO. X.—OPHTHALMOLOGY.

BY CHAS. S. TURNBULL, M.D.

(*Continued from page* 277).

Serious Effect of Calomel upon the Eye.

F. C. Hotz, M.D., of Chicago (*Archiv. Ophthal.*, Vol. XI, No. 1). In November, a railroad employé, aged thirty-eight years, consulted me for an affection of his right eye, which resembled, in every feature, an extensive burn of the ocular conjunctiva. The eyelids were red and swollen, especially the upper one, so much so, that the eye could be opened but very little. The conjunctiva of both lids were very red, succulent and roughened by enlarged papillæ. The retro-tarsal portions of the conjunctiva protruded in two thick, succulent folds when the lids were everted; and the ocular conjunctiva was also intensely red and swollen, so that its limbus projected considerably over the surface of the cornea. But what attracted my attention the most was a large, white crescent in the lower half of the ocular conjunctiva; its convex border reached down to the lower retro-tarsal fold; its concave border was parallel to and about 4 mm. from the margin of the cornea. The horns of this crescent extended upward around the sides of the cornea, and tapering off gradually, terminated in sharp points in the upper half of the eyeball. The surface of the crescent was markedly depressed below the level of the surrounding conjunctiva, and exhibited the whitish, dry, bloodless appearance of mortified tissue, which we usually find after a severe burn of the conjunctiva.

The lustre and transparency of the cornea were not disturbed; the iris, however, was discolored, the pupil was contracted, and dilated very irregularly, under the influence of atropia, on account of numerous fine synechiæ.

Upon inquiring into the origin of this peculiar affection, I received the following information: The patient's habits always had been very regular; he never had gonorrhœa or syphilis, and never had sore eyes.

The present trouble began two weeks ago, without any known cause, with swelling of the eyelids, redness of the eyeball, photophobia, profuse lachrymation, and some pain in and about the eye. He took some medicine internally (which, according to the prescription, contained quinine and morphine), but no medical application of any kind was made to the eye until two days ago. On that day his physician prescribed powdered calomel, which the patient's wife dusted into his eye by means of a camel's hair brush. He could not say how much calomel was thrown in the eye, but the application caused considerable pain, increased the flow of tears, and the tumefaction of the lids, and on the next morning his wife discovered on the eyeball a large white patch which, as she very positively asserted, was not there when she applied the powder on the preceding day. Under proper treatment, the iritis subsided quickly, and after the elimination of the eschar the extensive defect in the ocular conjunctiva was closed by cicatrization. At the expiration of three weeks the eye had recovered a normal appearance, with a regular and mobile pupil; the only evidence of the past trouble was a callous white scar in the ocular conjunctiva, below the cornea, with linear extensions around the sides of the cornea.

Remarks.—From the history of this case it is evident that originally the trouble was an acute iritis, with an unusual degree of chemosis. Upon a grave error in the diagnosis, calomel was prescribed, and its local application was followed by the lesion in the ocular conjunctiva so directly that the existence of a causal relation seems very probable. If the patient had been taking iodide of potassium, there would have been nothing remarkable in the unusually violent action of the calomel; for we know that under these circumstances it is converted into iodide and bichloride of mercury. But, as the patient had only taken a quinine mixture, I suspected the calomel was not chemically pure, the more so, as it was not

obtained at a first-class drug store. The chemist who examined the calomel for me reported the presence of considerable free hydrochloric acid; and to my further question as to the chemical changes such calomel might possibly suffer in contact with the lachrymal fluid, he replied that at the temperature of the human body chloride of sodium can convert a little calomel into bichloride of mercury, and that this alteration is greatly favored by the presence of free hydrochloric acid. The production of corrosive sublimate, of course, explains the caustic effect. When the calomel was dusted in the eye, I think the cornea was probably turned upward, and the powder was sprinkled on the lower portion of the chemotic ocular conjunctiva, and afterward rubbed into it by the pressure and movements of the swollen eyelids. This would account for the fact that the cornea escaped unscorched, and that the caustic action was most severe upon the more dependent portion of the ocular conjunctiva.

Two Cases of Malignant Tumor of the Sphenoidal Cavities, Implicating Vision.

(*loc. cit. p.* 52) Julian J. Chisolm, M.D., Baltimore. Within eighteen months two cases of malignant disease, supposed to have originated in the sphenoidal cells, have come under my observation, making four cases of this serious lesion which I have seen in the past ten years. In both of these last cases the disease seemed to have started on the right side of the bone, at the base of the skull. The eye complication was recognized as of post-ocular origin, and the lesion was located about the Sella Turcica, on account of the ophthalmoscopic appearances of the discs and the disturbed action of the eye muscles. In both cases the left eye became secondarily involved, both as to the functions of the optic nerve and the action of the muscles moving the eyeball. In each case the nose implication was subsequent to the eye trouble. The first action of the growth in its malignant development was to invade, by bone expansion, the optic foramen at the apex of the orbital cone, and impress the structures passing through this opening, then slowly involving contiguous parts, until both sides of the skull about the median line became affected. In both cases progress was slow, requiring many months for development. In each, treatment was unavailing to stop the steady growth of the disease, until one succumbed to the general poison, and in the other, life seems to be rapidly ebbing away amidst severe torture, which morphia in large doses and frequently repeated can scarcely mitigate. One case was in a boy 7 years of age, the other in a member of the medical profession aged 37 years.

While the two cases have this in common, viz., a malignant growth at the base of the skull, destroying sight, then developing in the direction of the face, filling the eye sockets, pushing out the eyeballs, invading the nares, and exhibiting a striking similarity in the disfigurement produced, there are symptoms peculiar to each. The youth suffered no pain whatever when the disease was making rapidly fatal progress; the older patient, on the contrary, has suffered severely from the very beginning of his trouble, and the intense agony of his every-day life has shown no mitigation. The younger case commenced with nausea and vomiting, with headache, before any other symptoms could be detected. When attention was called to the eye, for the rapid deterioration of sight, the cerebral symptoms of nausea and headache suddenly passed away. They did not return, although for sixteen months the disease, in its anterior development, filling up the face cavities with its cancerous growths, steadily progressed to a fatal issue. In the elder the nausea with vomiting appeared among the last symptoms, when sight had already been nearly destroyed, and when prominent growths were developing in the temple and in the roof of the mouth. In both cases the mind remained clear throughout. In both the disease extended from the right to the left side. In neither case was there any general paralysis nor any evidence of extensive encroachment by the growth in the direction of the cranial cavity. The loss of smell was secondary to that of sight in the youth, while it was retained in the older case, even when the disease had invaded the left orbit and had reduced vision in this eye to recognition of large objects, sight in the right having been utterly destroyed by pressure on the optic nerve. The youth suffered from an external squint with ptosis, the older with internal squint followed afterward by ptosis. In both the drooping of the lids of each eye became prominent.

A little more than a year after the time of the boy's first visit to Dr. Chisolm, he received a letter from his family physician, announcing the death of the boy. From this letter the following extracts were made: "Death apparently came from exhaustion and septic poisoning. The eyeballs protruded excessively, in hideous deformity. Bleeding, fungous masses protruded from each nostril, and also could be seen behind the palate. These emitted a most offensive odor.

His hearing was only implicated a few days before his death. The most wonderful part, to me, was the total absence of all pain. I was not able to make a *post-mortem* examination."

Tumor of Lachrymal Gland.

By Joseph A. White, M.D. (*loc. cit. p.* 62).

As tumors of the lachrymal gland are not very common, these few notes from my case book, in relation to the successful removal of such a growth, may be of some interest.

Mrs. E. Pye, a German lady, 60 years of age, has had a gradually increasing swelling at the outer part of the left upper eyelid, for more than a year. Of late its increase has been more rapid, the eye being pushed down and toward the nose, so that it is now (May 1, 1881), difficult to close the lid over it. At times the eye is quite painful and tender to the touch, is inflamed, and has a constant muco-purulent discharge. V = $\frac{20}{200}$ both eyes, with + $\frac{1}{8}$. R. V = $\frac{20}{20}$ with + $\frac{1}{10}$. L. V = $\frac{20}{50}$. Ophthalmoscope shows left optic nerve to be quite reddened, with hazy outline and large tortuous veins.

The case was evidently one of lachrymal gland tumor. On May 13th I removed the tumor through an incision made along outer third of edge of orbit, just below the brow. It was dissected out with probe-pointed bistoury and scissors. It was firmly attached above to the periosteum and below to the conjunctiva, and extended far back into the orbit, pressing upon the optic nerve. It was removed intact; was ovoid in shape, measuring one and a quarter inches in its length, and three-quarters of an inch in its transverse diameter.

Very little bleeding followed the operation. The wound was closed by stitches, leaving a small drainage tube at outer angle.

Though there were considerable ecchymosis and swelling of the eyelids and cheek, it healed kindly, and required little after treatment. Three weeks later it was entirely healed; the eye had returned to its position, its movements were free, the vision the same as before the operation, and the lid drooped slightly.

It is now six months since the tumor was removed, and the most careful examination can detect no signs of a recurrence; the eye and lids are perfectly normal, both in appearance and motion, and the vision has improved to $\frac{20}{20}$ with + $\frac{1}{10}$. My friend, Dr. Swan N. Burnett, of Washington, D. C., who, during the meeting of the American Medical Association, had examined the case, requested me to send him the tumor for microscopical examination when I should remove it. I sent him the specimen, and am indebted to his kindness for the following description of the tumor:—

Microscopic appearances, by Dr. Swan M. Burnett, Washington, D. C. The tumor is far from uniform in its histological structure. The connective tissue element is rather abundant in some parts, while in others it is very scant or entirely wanting. The cellular element, which is largely predominant, is likewise irregular in its distribution. It consists of rather large, round cells, with very thin cell walls, and large, granular nuclei. There are other cells, smaller, with small or no nuclei, which are distributed in somewhat large collections throughout the tumor mass. The characteristic form of myxomatous tissue is seen in abundance in all parts of the specimen. Cylinders and alveoli lined with cells in the characteristic arrangement of adenoma are met with, particularly near the centre of the section, passing through the tumor in a transverse direction. The remains of those structures are quite abundant, but in only one or two places have I been able to find them entirely intact and in anything like a normal condition. The alveoli are often filled with a hyaline mass (Becker), less frequently with round cells or granular matter.

From these appearances I think we are justified in describing the tumor as a myxo-adeno sarcoma. From an examination of this specimen alone it would not be possible to trace a general history of such tumors, but it tends to confirm the opinion of Becker* that all the forms of tumor of the lachrymal gland hitherto described are but different stages of the same morbid growth. It seems likely that they all begin as adenomas and that the various forms of degeneration—myxomatous, sarcomatous, colloid, encephaloid, etc., come on later. The appearances in this specimen differ from that of Becker's in this, that the degeneration was greatest toward the periphery, while in his the periphery appeared the more nearly normal.

Systematic Report on the Progress of Ophthalmology During the Third Quarter of the Year 1881.

By H. Magnus, M.D., *Archiv. Ophthal.*, Vol. xi, No. 1, under the head of General Ophthalmological Literature.

W. Sykes. *Clinical note and remarks on a Disease of the Eyes Peculiar to Colliers* (*Brit. Med. Journal* xlii, p. 77, July 16, 1881). The sight first fails in bad light, and grows gradually worse, till the pupils are dilated

* Weber, das Adenom der Thränendrüse. Bericht über die Augenklinik der Wiener Universitat, 1863-65.

and insensible to light, and only a perception of light remains, while nystagmus is well marked. Recovery takes place on exposure to light and air, without other treatment. The miners attribute the disease to bad light given by the safety lamp, but Sykes believes it to be toxic, from gases accumulating in the pits.

Fialkowsky. Ueber den Einfluss russicher Bäder auf das gesunde und kranke menschliche Auge. (*On the influence of Russian baths on the healthy and the diseased human eye.*) Wratsch, 1881, No. 9. The influence upon diseased eyes is greater than on healthy eyes. After the bath the pupils are somewhat dilated, or react sluggishly; both the far point (?) and the near point are slightly removed from the eye; the range of accommodation is, therefore, somewhat diminished. Visual acuteness suffers no change. Moreover, after the bath, conjunctival and retinal hyperæmia occurs; the secretion of mucus and tears becomes increased. Any inflammations present are intensified.

Gunn, R. M. *On the Continuous Electrical Current as a Therapeutic Agent in Atrophy of the Optic Nerve and in Retinitis Pigmentosa* (*Roy. Lond. Ophth. Hosp. Rep.* vol. x, pt. 2, p. 161, June, 1881). 1. In optic atrophy, Weiss' continuous current battery (the Foreaux-Smee; the elements are zinc and platinized silver), of 25 cells was the instrument used. The positive pole was placed on the closed eyelid, and the negative applied to the supra-orbital region, the top of the spine, and to a point just behind the mastoid process, in order to determine which position gave the greatest light impression. Five or seven cells were only employed at first. The supra-orbital region was the point selected in the majority of cases. The position of the poles was changed during the sitting, which lasted from five to six minutes. Of the eighteen cases thus treated, six improved, four were doubtful, and eight did not improve, or grew worse. Two of the six cases which improved returned some time afterward, with their sight as bad as before, and did not improve under further treatment. No really conclusive results were obtained, because of the smaller number of the cases, and the fact that this was not the sole method of treatment, as iodide of potassium, or strychnia, or other nerve tonics, are noted as having been given in all the cases but one.

Gunn considers, nevertheless, that when we compare the above results with those obtained where no galvanism has been employed, there must be a strong presumption in favor of its utility in certain cases. He is skeptical of the efficaciousness of iodide of potassium, and looks upon strychnia and the other nerve tonics as possibly of some use when combined with good food. He gives an analysis of the cases with reference to the question of prognosis, and the conclusion he arrives at is, that "he should give the most favorable prognosis when the patient is young or middle-aged, with recent failure of sight and present ability to count fingers, at least. Color-perception is possibly defective. The disc is white, but the large vessels are of normal size. There is no history of severe injury to the brain or spinal cord, but perhaps there are symptoms of locomotor ataxy.

Retinitis Pigmentosa.—Of the value of galvanism in this disease Gunn speaks hopefully. He reports four cases, in each of which there was a decided improvement. In case 1, the patient's condition on admission was, right eye, V = fingers at 3; left, V = $\frac{20}{70}$ with 36; and when discharged; right, V = $\frac{20}{70}$ nearly; left, V = $\frac{20}{40}$ nearly. Gunn refers to the literature of the subject, and draws attention to cases reported by Neftel and Dor, in which there was marked benefit by this treatment. He considers that the continuous current is capable of stimulating the conductivity of the optic nerve, both as regards the electrical current and the current originated in the impression produced upon its end-organs by means of light, and that this counteracts the degeneration of the nerve tissue which follows the absorption of light by the pathological pigment deposits. The defective blood supply also tends to produce further degeneration, and possibly galvanism has a temporary effect in dilating the blood-vessels, and so improving the nutrition of the tissue.

The caution to be observed in using the remedy is to begin with a weak current of five or seven cells for a short time, and then gradually increase if necessary.

(While observing the caution Gunn has just named, and after using the constant current in the same manner he has indicated, *i. e.*, as regards the position of the poles, I have, in specific paresis of the pupil and the forms of "neuritis optici," usually following these pareses, had decidedly satisfactory results in the way of making cures. I now consider electricity as an indispensable therapeutic agent in ophthalmology. With the positive pole on the closed eyelid, the negative pole on the top of the spine, I seldom employ more than five to six cells, and rarely excite more than the blue (weak) light impression, and if improvement be characteristic the light impression will change to white and yellow. T.)

The Laws of Inheritance in Relation to Disease. Lecture IV, delivered by Jonathan Hutchinson, at the Royal College of Surgeons of England. (*Medical Press and Circular*, Vol. XXXII, p. 22, July 13th, 1881.)

In his fourth lecture on "Laws of Inheritance," *Jonathan Hutchinson treats of heredity of retinitis pigmentosa.* It rarely appears at birth, though he believes the tendency to it to be present, but shortly develops and increases with age. Consanguineous marriages tend to strengthen the predisposition to the disease, and Liebreich has found it to be very common among Jews. Retinitis pigmentosa is allied to certain forms of choroiditis and to disease of the optic nerve. In retinitis pigmentosa the choroidal structure is interrupted and the retina is gradually obscured by a dense pigmentary deposit. The vessels shrink, and when once the series of events is established, it pursues a certain and inevitable course to the end. He then refers to the tendency of defects of the optical structure of the eye to be transmitted and become hereditary, and quotes cases in point, *e. g.*, myopic families. He further says: functional changes once duly fixed by pathological changes are transmitted from individual to individual, and that which at the outset ranked only as an idiosyncrasy may by and by develop into a determined disease. An instance of this is afforded by a form of amaurosis due to the excessive tobacco smoking, the tobacco here acting not as the actual producing cause of the disease, but as an excitant of the tendency to defect when once originated.

Correspondence.

Medical Legislation.

ED. MED. AND SURG. REPORTER:—

In a recent number of the REPORTER you favored the profession with a few very valuable "Hints Concerning Medical Legislation;" and as these apply specially, no doubt, to the profession in Pennsylvania, a few additional remarks may be useful. We must educate ourselves; and we believe that a much larger space should be given to this subject in our medical journals. At the same time we must educate our legislators and the people; and this can be done best through memorials, correspondence and our daily newspapers. The school is large and there are in it many dull scholars. The teaching thus far may not have been the best, but we have made progress. Nearly every practitioner in the State has registered, under the recent act of Assembly.

The failure of the committee appointed by our State Medical Society to secure the passage of an act to provide for a State Board of Health has restricted the committee on medical legislation, appointed by the same Society, to a kind of legislation which has necessarily in it the elements of weakness. A standing argument against the establishment of a Board of Health has been the creation of a new office, to be filled by partisan influence. The Committee on Medical Legislation understand this subject quite well, and have not been disposed to ask for a Board of Medical Examiners for the State, as this would give rise to another office or bureau, to be filled in a similar manner. Moreover, it is agreed by these committees, that there is really no necessity for two boards; and further, that the efforts of the profession should be centred upon one object, the organization of a State Board of Health, with authority to supervise the registration of medical practitioners. To *load down* a measure of this kind with the minutia of registration may not be politic, and hence a supplement to the present registration act has been prepared, transferring the duties now imposed upon the faculties of our medical colleges, to a Board of Health.

The registration act referred to (see REPORTER, June 25th, 1881), is *prospective* in its leading features, and if we should not be able to secure the passage of a supplement, it will produce good results in the counties in which the profession take an interest in its enforcement. A grand jury cannot object to registration; it will be more difficult to stop a bogus diploma man, or a non-graduate who has been in the continuous practice of medicine since 1871. A retroacting law, which would cut off ten per cent. of the present practitioners, even if it could be passed, would be inoperative, without authority vested in a board of health or some other body of men to enforce it.

At the bottom of this whole subject is the fact that our government does not favor a high standard in the profession. The independence of the States prepares the way for sectarian medicine, and for any number of chartered medical schools of low grade. A half-dozen pretentious men, without education and without money, can obtain a charter for a medical school in any of our States, and do a thriving business. We have some, I fear many, such institutions in our country, and hence we are brought to the conclusion that the degree of Doctor of Medicine can no longer be taken as conclusive evidence of fitness to practice medicine. A license issued by a competent board of examiners has become a necessity.

Carlisle, Pa. R. L. SIBBET, M.D.

News and Miscellany.

Proposed International Hygienic Convention.

Dr. L. de Csatary proposed, at the late Geneva Congress, the formation of such a convention, for the purpose of securing uniformity in national legislation affecting the public health. It is suggested that an international committee of surveillance should be created to secure the observance of such hygienic measures as might be adopted in common by the various nations leagued together. A committee was appointed to present the matter in due shape to the next congress, at the Hague.

American Academy of Medicine.

The seventh annual meeting of the American Academy of Medicine will be held in the Hall of the College of Physicians, Thirteenth and Locust streets, Philadelphia, on Thursday, October 26th, at three o'clock, P.M. The President, Dr. Traill Green, of Easton, Pa., will deliver an address at 8 P.M., Thursday, at the College of Physicians, to which the medical profession is invited.

RICHD. J. DUNGLISON, *Secretary.*

John Hunter.

Dr. Oliver Wendell Holmes pays the following tribute to John Hunter: "A great comparative anatomist, a great physiologist, the creator of a vast museum, the author of innumerable original observations of interest to medical science, a surgeon of distinction, a man of powerful native genius, insatiable in thirst for knowledge, indefatigable in accumulating it, his works have been treated as quarries by those who came after him, as the Coliseum was used to build up palaces for the Roman nobles of later ages."

A Rescue Boat Race.

We learn from the *Lancet* that at the late Clevedon regatta, a novelty was introduced in the shape of a "Rescue race." The idea was originated by Dr. Richardson, F.R.S., who is staying at Clevedon, who gave the first prize, of $5.00, Mrs. Richardson giving the second, of $2.50. The whole of the competing boats had to be stranded high and dry upon the beach, and at a given signal the men had to get them launched, and then proceed to try to pick up one or two objects, representing drowning men floating about three-quarters of a mile out in the bay.

Items.

—The Very Rev. Dr. Egan has been appointed Rector of the Catholic University, and a Fellow of the Royal University of Ireland.

—Dr. Strange, the President of the British Medical Association, has been elected an honorary member of the Société Française d'Hygiène.

—From the *British Medical Journal* we learn that, from the annual report of the receipts and expenditures of the City of London, just published, it appears that the cost of entertaining the members of the International Medical Congress to the *conversazione*, last year, in the Guildhall, amounted to $10,495.

—In the *Wiener Med. Wochenschrift*, No. 35, Dr. Ludwig Klaar reports a fatal case of perforation of the œsophagus, due to a wood-shaving having become impacted in the gullet at the level of the bifurcation of the trachea. The thoracic aorta was eaten into, and this led to the man's death by profuse hemorrhage.

—The municipality of Turin lately opened a competition for the best treatise on hygienic science as applied to the requirements of rural districts. The prize has been awarded, by the jury charged with the decision, to Dr. Layet, professor of hygiene at Bordeaux. It consists of a sum equal to about $500.00.

OBITUARY NOTICES.

WILLIAM PIERSON, M. D.

Dr. William Pierson died at his residence in Orange, N. J., Oct. 1st, in the eighty-sixth year of his age. He was born in 1796, was graduated from Princeton College in 1816, in the same class with the late Bishop McIlvaine and ex-President Maclean, of that college, and began the practice of medicine in 1820. He belonged to a family of physicians, comprising his grandfather, Matthias Pierson; his father, the Hon. Isaac Pierson, for some years a member of Congress; himself, and his son, William Pierson, Jr., all of Orange. He was for thirty years the Secretary of the New Jersey Medical Society, and afterwards its President, and at the time of his decease was the oldest physician of the State. During his long life he was prominent in public matters, as well as his profession, having been a member of the New Jersey Legislature between 1835 and 1840, and from 1849 to 1852 Sheriff of Essex county, in which office he was succeeded by his brother, Edward Pierson, and the first mayor of the city of Orange.

—Dr. Frazer, ex-member of the Canadian Parliament and a prominent physician, of Welland, Ontario, is dead.

QUERIES AND REPLIES.

In reply to query of "J. N. R., Pa.," in your issue of May 6th, 1882, as to whether any of your readers ever heard of twins living to maturity and both having families, I would say that in my practice there are *two* families having twins grown up, all four of whom have children; are healthy and prolific. R. B. E.

McKnightstown, Pa.

MARRIAGES.

BAILEY—BANCKER.—On Wednesday, Oct. 4th, at the residence of the bride's parents, No. 430 Clinton Avenue, Brooklyn, by the Rev. Emory J. Haines, Fred. D. Bailey, M.D., of New Milford, Penn., and Margaret M., daughter of William D. Bancker.

BALLANTINE—WALKER.—On Wednesday evening, Oct. 4th, by the Rev. H. L. Duhring, Rector of All Saints' Church, at No. 1700 S. Tenth street, C. Hamilton Ballantine, M.D., and Miss Clara A. Walker, both of this city.

CORRY—CORTELYOU.—In Brooklyn, Oct. 3d, by the Rev. Henry A. Davenport, of Bridgeport, Albert M. Curry, M.D., and Phebe D. Cortelyou, both of Brooklyn.

GRIFFITH—JENKS.—On Thursday, October 5th, in the Woodlands Presbyterian Church, Forty-second and Pine streets, by the Rev. Dr. Benjamin Griffith, assisted by the Rev. Dr. Crowell, Dr. J. P. Crozer Griffith and Julia E., youngest daughter of Barton H. Jenks, all of Philadelphia.

HARVEY—GREEN.—At East Orange, N. J., Oct. 3d, 1882, at the residence of James C. Bayles, by the Rev. Alfred Yeomans, D.D., Katharine Green, daughter of the late Edward Green, of New York, and Dr. Thos. W. Harvey, of Orange, N. J.

NILSEN—WHITTEMORE.—In New York, on Tuesday, Oct. 3d, at the residence of the bride's parents, by Rev. Dr. William M. Taylor, Jonas Rein Nilsen, M.D., and Laura, daughter of Thomas W. Whittemore.

DEATHS.

ANDERSON.—At Kingston, N. Y., on Saturday night, Sept. 30th, Dr. Wm. C. Anderson, of Staten Island.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

SANITARY AND OTHER FEATURES OF THE HUMIDITY OF HEATED AIR.

BY THOS. S. SOZINSKEY, M.D., PH.D.,
Of Philadelphia.

The disturbing influence of atmospheric vicissitudes on the system is, both directly and indirectly, a potent cause of disease and death. Direct and clearly manifest effects of it are observable in the marked prevalence of inflammatory affections of the chest, in winter, and of diarrhœal affections in summer; and those of gradual onset or of an indirect character, are doubtless quite as important, though not very obvious. In the so-called temperate zones of the earth, it would seem that multitudes are almost inevitably doomed to succumb to "stress of weather," to use an expressive nautical phrase. It is, perhaps, impossible to entirely prevent harmful perturbations of the system of such origin. Due regulation of the clothing, and mode of life in general, is, of course, powerful for good; but all efforts to withstand and to shun external conditions of a nature prejudicial to health are far from being perfectly successful.

Of the various expedients resorted to for the purpose of circumventing special harmful atmospheric vicissitudes, or conditions, it is more than probable that some are not free from harm in themselves. Certain changes produced in air artificially heated is one of these, and to it the remarks which succeed will be devoted.

Heated air, in its various aspects, is so extensive a subject, that I will not attempt to do more at present, than speak of some features of its humidity or degree of moistness, a matter to which little study is given, although it assuredly merits the attention, not only of physicians, but of people in general.

The hygrometric condition of the air and its variations, even apart from their effects on the economy, are indeed somewhat abstruse matters, but not to such a degree as is generally supposed, certainly not so markedly so as to be beyond the comprehension of any one almost, who really wishes to understand them. A careful perusal of the remarks I shall make below will, I believe, enable one to gain an insight into most of the chief features of them, besides their bearings on health, which are of interest to the physician and sanitarian.

It is hardly necessary to say that the atmosphere consists essentially of nitrogen, oxygen, carbonic acid and aqueous vapor. The proportion of each of the first three ingredients or constituents of it is nearly always and everywhere the same—a given amount of it contains about 79 parts of nitrogen, nearly 21 of oxygen, and about .04 part, or 4 parts in 10,000 of carbonic acid; but the proportion of the last, in a given amount of it, varies very much. The possible amount of aqueous vapor present depends on the temperature. When the temperature is high, much more may be present than when it is low. Thus a cubic foot of air, at a temperature of 90°, may contain over fifteen times as much as the same bulk at a temperature of 5°, an enormous difference.

In this connection it is expedient and well, I think, to give the following useful table, showing

the possible amount of vapor present in a cubic foot of air at different temperatures:—

Temp.	grs. of vapor to c. f.	Temp.	grs. of vapor to c. f.
0	.78	45°	3.64
5°	.93	50°	4.28
10°	1.11	55°	5.02
15°	1.32	60°	5.87
20°	1.58	65°	6.87
25°	1.87	70°	8.00
30°	2.21	75°	9.31
32°	2.37	80°	10.81
35°	2.62	85°	12.53
40°	3.09	90°	14.50

When a given amount of air of a certain temperature contains as much moisture as can possibly be present without precipitation, it is said to be saturated. Now, taking the amount of moisture present when the air is saturated, to be represented by 100, the degree of saturation, or, in other words, the relative humidity may be expressed in parts of 100. Thus, as a cubic foot of air at 70°, when saturated, contains 8 grs., if there are only 4 grs. present in it, the degree of saturation, or relative humidity, is indicated by 50. Then, of course, if the relative humidity of air, at a temperature of 70°, is, say 75, it contains 6 grs. of moisture to the cubic foot. Evidently, if the temperature and relative humidity are given, it is easy to calculate the precise amount of moisture present in a cubic foot of air, when a table of the possible amount present at different temperatures is at hand; all that one has to do to determine it, is to multiply p, the possible amount present, by r, the relative humidity, and divide the product by 100, or the amount of moisture present in a cubic foot is $= \frac{p \times r}{100}$.

I need not explain at length how to determine the relative humidity. It is sufficient to say that to do so, it is necessary to have a hygrometer, say Mason's (the one in general use), an instrument by which the difference between the actual temperature and the temperature at which the air should be so as to be saturated with the moisture present in it, or at the dewpoint, is indicated. This difference being known, the relative humidity is found by referring to a table, the nature of which I need not explain. The hygrometer consists essentially of two thermometers placed on a rest at a distance of two inches or so from each other, the bulb of one of which is covered thinly with a cotton wick, which is kept moist through imbibing water from a cup or other vessel placed near by. Being neither expensive nor hard to operate, it should be in more general use than it is. The absence of it, even in hospitals, schools and such institutions, indicates how extremely few are alive to the value of it.

To any one who has carefully read what precedes, it is evident that if air is artificially heated, the relative humidity of it must necessarily be altered. Thus, if the air of a room the relative humidity of which is 50 be raised from a temperature of 30° to 70° the relative humidity will then be 14.8. Here the problem runs thus: If air of a temperature of 70° contains 1.185 grains to the cubic foot, what is its relative humidity? The answer is obtained by dividing p, the possible amount of moisture present at 70° (8 grs.) by a, the actual amount present (1.185 grs.) and 100 by the quotient or the relative humidity is $= \frac{100}{p \div a}$.

Now, if in a room we have 1000 cubic feet of air, the temperature of which is 25° and the relative humidity 50°, and we raise the temperature to 70°, how much moisture must be added in order to have the humidity still at 50? The answer is 3.065 grains to the cubic foot, or 3065 grains in all, which is 6.73 fluidounces, the weight of an ounce of water being taken at 455 grains. Then, of course, if the 1000 feet of air were changed hourly, it would be necessary to have 161.5 ounces or about five quarts of water evaporated every twenty-four hours.

Again, if in a house we have 20,000 cubic feet of air, the temperature of which is 25° and the relative humidity 50, and we raise the temperature to 70°, how much moisture must be added in order to have the relative humidity still at 50? The answer is 61,300 grains or 134.7 fluidounces, which is somewhat over four quarts. Then, of course, if the 20,000 feet of air were replaced hourly, it would be necessary to have 3232.8 ounces or about 25 gallons of water evaporated daily.

If the temperature be as low as 10°, and of a humidity of 25, the air of a house of a capacity of 30,000 cubic feet, heated to 75°, and rendered of a humidity of 60, would call for the evaporation of 5.3 grs. to the cubic foot, or nearly 11 quarts in all. Then, of course, if the 30,000 feet be replaced hourly, the evaporation of 264 quarts or 66 gallons would be needed every 24 hours.

Evidently it would require a large pan and a high heat beneath it to evaporate sufficient water to properly hydrate the air of a large house the temperature of the air of which is kept at 75° on a frosty day. The little pan which may or may not be found in connection with a heater

would be of little value; it would require over a hundred such to serve the purpose.

In order to gain even a moderately correct idea of the amount of moisture which must be added to the heated air of a house so as to keep it at a reasonable degree of humidity, it is necessary, among other things, to form an estimate of the amount of air which should pass through it during a given length of time.

Now, to arrive at even a moderately correct conclusion as to the amount of air which should pass through a house hourly, or daily, it is necessary to be aware of the number of inmates, and also of any other source of contamination of the air, such as the burning of gas, which are present.

Although there is sufficient reason for holding that a person should have 3000 cubic feet of fresh air per hour, the amount one contaminates through the breath and otherwise, to a really injurious degree, may be set down at 1000 cubic feet per hour. The amount of carbonic acid given off by the lungs alone of an adult being about 5 per cent. of the 15 cubic feet consumed by such a one, on the average hourly, or $\frac{3}{4}$ of a foot per hour, would consequently be sufficient to cause nearly 5 parts to the 10,000 of it to be present after a person had been in an air-tight room containing 1000 cubic feet for an hour—a proportion of it, whether of itself or of the organic matter which accompanies it, which would cause lassitude and other undesirable effects. Dr. Parkes regards more than 6 parts in 10,000 as decidedly too much.

If two persons are in a room of a capacity of 1000 feet, it follows from what has just been said that all the air within it should be replaced every half hour; and if four are present it should be replaced every quarter of an hour—a thing which can hardly be done without causing injurious drafts. With the contamination caused by the skin as well as the lungs taken into account this estimate is low.

The air of a room may, under favorable conditions, be changed three times per hour, but it is unusual, I believe, for it, in one of a capacity of say 3000 feet, one 17.33 feet in length, the same in breadth and 10 feet in height, to be replaced even hourly; and rarely is any great effort made to ventilate any room to meet the requirements of the number of persons present—a very serious sanitary dereliction.

Taking a heated room of a capacity of 2000 cubic feet, the air of which is replaced about hourly, and in which there are four persons, let us consider some of the hygrometric features of it in detail. Now, if we take the temperature of the external air to be 35° and the humidity 70—the average temperature and humidity from the first of December to the end of March, at Philadelphia—and the temperature of the air within to be 70°, it would be necessary to have a pint of water evaporated hourly in order to keep the humidity at about 65—a fair degree of humidity when the temperature is 70°. Now, as the amount of moisture exhaled from the four persons present may be placed at four ounces per hour—a low estimate undoubtedly, when the air around is dry and warm—the amount to be supplied by artificial evaporation is reduced to three quarters of a pint hourly. If no moisture be evaporated artificially the degree of humidity would be nearly 34. If the air without be of a temperature of 35° and of a humidity of 70, when heated to 60°, the humidity would be about 27. If an addition of 4 ounces be made to every 2000 feet, the humidity would be about 40. With a temperature of 70° and a humidity of 34 it would be necessary to evaporate about 11 ounces of water in order to bring the humidity of 2000 feet of air up to 65; and with the temperature at 60° and the humidity at 40 it would be necessary to evaporate about half a pint in order to bring the humidity to 65.

It appears, then, that even if a room of a capacity of 2000 feet contains four persons and has a complete change of air only once every hour, if the temperature is kept at 65° and the humidity at 70, it is necessary to evaporate a large amount of water in order to keep the humidity at 65.

A fact worth noting here is, that sometimes, in a badly ventilated room in which there are many persons, the degree of humidity may be high even if no moisture be added artificially. Thus, in a room the air of which is changed once every hour, and in which there is a person to every 200 cubic feet of its capacity—an allowance which is not reached in some schools and other institutions—the air without being at a temperature of 50° and of a humidity of 70, and the air within at a temperature of 65°, its humidity will be about 83.

From what has just been said, it follows that the amount of moisture which should be added to the air of a heated room when unoccupied, to have it at a proper degree of humidity, may be uncalled for when a number of persons have been present for awhile. It is wrong, then, to go on supplying the same amount of moisture to the air of a room regardless of the number of its occupants.

In this connection it is proper to state that the moisture which is supplied artificially to the air of a house should, as a rule, be supplied to each room according to its requirements. This should be done through an evaporator, or some special arrangement by which evaporation can be facilitated. Supplying the moisture to a whole house through an evaporating pan placed in a heater, is a very unsatisfactory plan, for, unless the temperature is at the same degree in each department, the degree of humidity varies. Thus, if a sufficient amount of water be evaporated in this way to keep the air of a room in which the temperature is 70° at a humidity of 65, the air of a room in which the temperature is 60° would be far too damp, it would be almost saturated.

In a room the air of which is kept warm through a heater or other ordinary means, it usually happens that the temperature is very unequal in different parts of it, and the same must be at least equally true of the humidity. Thus, while the temperature close to the register is over 100°, it may be under 60° at points distant from it, and at least an equally marked difference of humidity is inevitable. The due regulation of the humidity of such a room is an absolute impossibility. And are not the majority of rooms such? It is unfortunate that any room should be such, but more especially a large one, in which many assemble, as a schoolroom.

The difference in the temperature, as well as the hygrometric condition of different parts of a room heated artificially, depends greatly on the character of the walls, and the facility with which currents of air may both escape and enter, but greatly also on the temperature of the air at the source of heat. When the temperature of a large room is kept up through the entrance of heated air, there should be more than one place for it to enter; there should be many; and, in case of any room, it is wise to have a large volume of air of a moderate temperature to enter, rather than a little only at a very high temperature.

Now, as a matter of fact, one feels warmer in a moderately moist than in a very dry air, of any temperature. Very dry air, especially when warm, tends greatly to cool the body, by inducing speedy evaporation–a chilling process. Air of a temperature of 60° and of a humidity of 80 feels warmer than air of a temperature of 70° and of a humidity of 40. From this, and the fact that when a room is occupied for a little while the relative humidity is increased, it follows that the temperature should be reduced somewhat after occupancy.

The statement made above, that air of a temperature of 60° and of a humidity of 80 feels warmer than air at a temperature of 70° and of a humidity of 40 is one which I desire to emphasize. The truth of it admits, of course, of experimental demonstration; but it can be equally as well shown, mathematically. This I will do, taking into consideration only the impression produced on the system by each quality of air through respiration, what is true of it being more emphatically true of that produced through the skin.

Now, it is necessary to premise that the specific heat of air is .237, that a cubic foot of air of a temperature of 60° weighs 536 grs., and one of air at 70° weighs 526 grs., that there are 7000 grs. in a pound. that 966 heat units (the unit of heat is the amount required to raise one pound of water one degree) are necessary to evaporate a pound of water, and that exhaled air may be taken as of a temperature of 90°, and of a humidity of 100. In passing through the lungs, the amount of heat necessary to bring a cubic foot of air at a temperature of 60° and of a humidity of 80 up to 90° and to the point of saturation, is .544 heat unit, or $30° \times \frac{536}{7000} \times .237$; and as the evaporation of the 10.234 grs. of moisture necessary to produce the equalization in moistness calls for 1.412 heat units, the whole amount of heat abstracted from the system in the process is 1.956 heat units. Again, in passing through the lungs, the amount of heat necessary to bring a cubic foot of air at a temperature of 70° and of a humidity of 40 up to 90° and to the point of saturation, is .356 heat unit, or $20° \times \frac{526}{7000} \times .237$; and as the evaporation of the 11.65 grs. of moisture necessary to produce the equalization in moistness calls for 1.608 heat units, the whole amount of heat abstracted from the system in the process is 1.964 heat units, which is .008 heat unit more than in the former case.

If the degree of humidity is productive of decided effects on the economy in health and disease, the considerations which precede would seem to indicate that heating the air we breathe may be a source of harm. That the degree of humidity has much influence on the system, cannot be doubted; and that it is, under ordinary circumstances, as injurious when very low as when decidedly high, is, perhaps, equally certain. No doubt very dry warm air has a deleterious effect on the functional action of the skin and other parts. The unpleasant effects of it

on the eyes is familiar to every one. But the direct constitutional injury which may be produced by it is probably less in importance than the injury produced indirectly, though being markedly unlike the external air. One who enters or leaves a room the air of which is very warm and dry, on a cold day, sustains a more or less violent strain of different functions. As every one must move in and breathe the air out of doors, it is wise not to render it injurious by living habitually in a very unlike artificial atmosphere. Better to rely to a considerable extent on regulation of the clothing, than to raise the temperature of the air artificially to a high figure.

It has been affirmed that an addition of moisture to heated air is simply not wanted. This comforting conclusion is supported mainly by two reasons, to wit, that organic matter is removed speedily, and is uninjurious in proportion to the degree of dryness of the air, and that as expired air is always of a temperature of about 90°, and saturated, the impression on the system, so far as the humidity is concerned, when unheated, is essentially the same as when heated.

Now, these reasons are unsatisfactory. Little or much organic matter is expected to be present in the air of an inhabited room, according as it is or is not properly ventilated, and it is unlikely that any which may be present would be rendered more injurious within both a reasonable length of time and a reasonable degree of humidity. The statement that the air issues from the lungs at the same temperature and humidity, whether it is cold or warm, may be true, but even if a like impression were produced on the lungs by air of any degree of humidity when unheated as when heated, there is a difference of impression made on the surface, and through it on all parts of the body, which is of great significance. Then the state of the air without, as regards humidity, is not always the best. It may not be wise to keep the humidity of heated air very high, but assuredly it is also unwise to keep it very low. It is well to keep it at a moderate degree.

It being so difficult to keep the humidity of highly heated air at a proper degree, it is judicious, for this reason alone, to be satisfied with a moderately low temperature, to let it be, as a rule, from 60° to 65°. Especially is it wrong to have the air highly heated when the weather is very cold. The sensation of heat and of cold being to a great extent relative, the temperature of the air within should be regulated somewhat according to the temperature of the air without, unless a person is in it constantly. In truth, the craving for very warm air is induced largely by inactivity and habit. One can easily render himself chilly in air at 70°, by exposing himself awhile to air at 80° or 90°.

RIGIDITY OF THE OS UTERI.

Read before the Burlington Co., Medical Society, October 10th, 1882.,

BY WILLIAM H. SHIPPS, M.D.,

Of Bordentown, N. J.

Not the least among the many operative causes tending to retard or make difficult the act of parturition, may be mentioned "Rigidity of the Os uteri." This complication of labor may be dependent upon one of several factors; namely: Nervous or vascular excitement, induration of the os uteri, scirrhous or carcinomatous condition of the cervix, or entire obliteration of the cervical canal.

Examples of the first class are not infrequently met with, and, as a rule, offer no permanent barrier to the final successful consummation of labor. The other varieties, on the contrary, though of rare occurrence, act as formidable obstacles to the free passage of the child, and almost invariably necessitate the intervention of art.

Illustrative of one of the last named varieties, I ask the attention of the Society to the following case recently occurring in my practice.

At daybreak on the morning of August 17th, 1882, I was called to attend a Mrs. C., 42 years of age, of good physique, in her thirteenth labor. It may be well to mention the fact that I had attended the woman on two former occasions, the last being in July, 1881, at which time she was delivered of twins at seven months; the cause of this premature delivery was malposition of the placental mass, which almost entirely occluded the mouth of the uterus. Delivery was accomplished with difficulty, the woman being almost exhausted by the profuse hemorrhage. Fortunately, however, she made an excellent recovery, and was spared to figure in a different rôle the year following.

On my arrival at the house at this, her last labor, I was informed by the nurse that she had been in pain since midnight, and that they had summoned me on account of the increasing severity of the pains, and as they supposed, the probable speedy termination of the labor. At this time the pains were of moderate severity, and occurring at intervals of five or ten minutes; the mouth of the womb was dilated to the extent of about one inch in diameter, waters presenting,

through which the finger readily detected the head of the child occupying the third position of the vertex. On making the examination, I was struck by the peculiar conformation of the uterine orifice. Instead of the natural elastic feel characteristic of the normal condition, I noticed that the anterior and posterior lips, throughout their entire extent, appeared to be in a state of hypertrophy, forming a well defined band or ring of hard, inelastic, cartilaginous tissue, so unyielding in its nature as to preclude the possibility, as I thought, of its being overcome by natural causes. This hardness, though general, was more pronounced at a point commencing at the superior portion of the left lateral division of the os, and terminating at a corresponding point on the under or inferior surface. Besides this abnormal hardness, there was a want of uniformity in the contour of the uterine mouth, its edges being rugged, uneven and nodulated, probably the remains of old cicatrices resulting from lacerations in former pregnancies.

After assuring myself that no apparent progress was being made, I left her, to return at 10 A.M. Examination at that hour showed that no perceptible advance had been made. I made repeated attempts at dilatation, by means of the fingers, but with indifferent success. At 12 o'clock the waters ruptured spontaneously, the head still being high up in the pelvis. I then began the use of chloral, giving thirty grains in all, during the next two hours. At 4 P.M., no advance being evident, I called Dr. H. H. Longstreet in consultation, who confirmed the diagnosis, and agreed with me that, as the woman's physical condition was yet good, and she evidently possessed considerable reserve force, little would be lost by waiting a few hours longer, at the expiration of which time, if no improvement were manifest, incision of the uterine orifice would be made, with the hope of finally overcoming the obstruction. I visited the patient just before midnight, and found that relaxation was commencing at the right superior portion of the mouth. Before returning home I authorized the nurse to send for me immediately if my services were necessary. I was called at 5 A.M.; pains had increased in severity, with slight advance of the head, and the mouth of the womb relaxing throughout its entirety. At 7 A.M., a strong expulsive effort brought the head into the world. By this time the woman was pretty well worn out and had to be strongly urged to her duty. Despite my utmost efforts, some fifteen minutes elapsed before the body was born. The child was dead, finely developed, and weighed 13½ pounds. A few moments later I attempted the removal of the placenta, but found that I could barely touch its border with my index finger. I waited an hour, meanwhile practicing the so-called method of Crédé, and, as I supposed, that of every one else, without making the least impression.

The intervals of my attempts were filled in by efforts at restoring my patient to a state of consciousness, who about every ten minutes would fall into a condition of syncope. Finally, by way of complicating matters still further, she went off into a convulsion, which happily was of short duration. Concluding that a speedy termination of the labor was now indicated, I brought the woman to the edge of the bed, and introducing my hand into the uterus found the placenta high up in the womb and firmly adherent three-fourths of its extent; carefully breaking up the adhesions, I was successful in removing it entire. Examination now showed that nature had accomplished her end, not only by a gradual softening down of the hardened tissue, but had actually forced asunder the unyielding band, lacerating it, at several points, without seeming harm to the woman, as the sequel showed. The woman made a speedy and satisfactory recovery.

In reviewing this or analogous cases, the following questions might very naturally suggest themselves:—

1. What part do nature, venesection, chloral or other drugs and dilatation, play, in overcoming the obstruction?

2. When is operative interference necessary or justifiable?

3. The method of interference.

With regard to the first, I am fully persuaded in my own mind, that nature alone, in the case just cited, was the active and controlling agent in overcoming the difficulty. Venesection, medicines, and digital dilatation, though of unquestioned benefit in the ordinary forms of rigidity, are in these cases not only useless, but of positive harm, serving only to depress and harass the already exhausted woman. At times the power of nature in overcoming mechanical rigidity is simply wonderful; and yet, while accepting the truth of this proposition, we are not to suppose for an instant that our duty is simply to watch the gradual development and beautiful unfolding of nature's processes. The strength of the woman must be sustained at all hazards; lose sight of this, and nature sinks, helpless, before her task. This we can accomplish by means of the free exhibition of nourishing food, than which there is nothing better than beef tea,

milk and coffee, preferably the latter, and if occasion requires, brandy. The condition of the bladder and bowels must not be overlooked. But suppose that nature fails, then we come to consider our second query—

When is operative interference necessary or justifiable?

This question is not so readily answered. Whenever the condition of the woman is such as to lead to the belief that longer delay will undoubtedly imperil her safety, the time has come to interfere. What, then, are the indications pointing to this end?

So long as the woman's condition, as manifested by the pulse, skin and tongue, is good, wait!

If the cervix shows signs of yielding, wait!

If the pressure of the child's head upon the soft parts of the mother be not sufficiently great to jeopardize their integrity, wait!

But suppose the woman shows unmistakable evidence of exhaustion; the pulse is irritable and weak and increased in frequency, there is hemorrhage, attacks of syncope, or convulsions, fears are entertained lest harm may come of the continual pressure of the child's head; then the time for waiting has passed, and that for action is at hand. This brings us to a consideration of the last question:—

How shall we interfere?

The operation is unattended with pain, easily performed, and comparatively harmless. The patient is placed upon her left side, or back, and brought to the edge of the bed.

During the absence of a pain the index finger of the left hand is carried to that portion of the os uteri intended to be incised; the flat surface of a probe-pointed bistoury or hernia knife should be passed along the palmar aspect of the finger, to the required length, the knife is then righted, and a sawing motion is made from within outward and upward; some insignificant hemorrhage usually follows, but rarely gives rise to any serious embarrassment. The best and safest sites for operating are the lateral sides or the under border of the orifice; three incisions, as a rule, are all that will be required, while in not a few cases one or two will suffice. During the passage of the child these incisions will probably be somewhat extended; when the operation is performed imperfectly or too early, this accident will invariably follow. It must be admitted that the operation of incision, like every other surgical procedure, has its opponents as well as its advocates; among the former appearing the names of such distinguished authorities as Goodell and Albert Smith, of our own countrymen, and Baudelocque, Dubois, and Madame La Chapelle, abroad. Some of these authors enthusiastically proclaim dilatation by means of the colpeurynter of Braun, or the rubber bags of Dr. Robert Barnes, to be the remedy or agent par excellence for overcoming the non-spasmodic form of rigidity, and as emphatically protest against the use of the knife in these cases, as rendering the patient liable to serious laceration of the uterine body, with septic absorption as a probable sequence.

In answer to these objections, it is only necessary to state the familiar fact, that in almost every normal labor, particularly that of primiparæ, laceration more or less extensive occurs, followed only in rare instances by evidence of septic poisoning. Again, the forcible dilatation of any structure, especially if the operation be performed with any degree of rapidity, is necessarily always attended by a break in the continuity of the muscular fibres, if not actual laceration of the tissues involved. This I claim follows every attempt at dilatation of the os uteri, whether the force applied be a natural or artificial one; dilatation is, therefore, not exempt from the very dangers it pretends to avert. I am not to be understood as advocating the operation of incision in all cases of physical rigidity, but only when, after allowing nature a fair trial, she is found unequal to the task before her. It was my intention to consider in detail the other varieties of uterine rigidity, but fearing to trespass upon your time to that extent, I have postponed their notice until later.

NOTES ON HEADACHE AND SICK HEADACHE.

BY G. C. SAVAGE, M.D.,
Of Jackson, Tenn.

Through the kindness of Dr. Nicholls, of Philadelphia, and Dr. Taylor, of Corinth, Miss., I have had the pleasure of reading the "Notes on Headache," by S. Weir Mitchell, M.D., published in the REPORTER, Feb. 6th, 1875, one of the numbers to which my unnamed friend in Texas called my attention in a late issue of the REPORTER. I have not been able to procure the number issued Aug. 1st, 1874. If my Texas friend will be kind enough to send this number to me, I will appreciate the favor, and will return the journal and cost of sending.

I cannot infer the object my friend had in view in calling my attention to the "Notes" of Dr. Mitchell, unless it was that I might see that

the theory I had claimed as my own, by right of discovery, had been advocated by Dr. Mitchell eight years ago. I naturally sought anxiously for the journals containing Dr. M's. notes, that I might see what this man, for whose medical lore we all have the greatest respect, had written on sick headache. Although I have not seen the journal published Aug. 1st, 1874, I infer from the one published Feb. 6th, 1875, that in the former he had written nothing indicating that he had entertained any views, as to the causes and cure of sick headache, coinciding with mine as published in the REPORTER of July 29th, 1882, since he, in his February "Notes," after stating in his first paragraph that he would now consider "some forms of this disorder [headache] which are either undescribed or ill-described," says, in the beginning of his second paragraph, "and first as regards the headaches of some eye strain." Further on in the second paragraph he says that he stated in his paper published Aug. 1st, 1874, "that astigmatism, disorders of accommodation of the eye, and defects of power to converge or diverge, the optic axes, are alike the causes of *head pains;*" but he does not say that in that paper he thought that *sick headache* depended on these causes; and certainly he does not teach this doctrine in his February "Notes," before me.

The "Notes" by Dr. Mitchell are worthy of greater consideration, doubtless, than they have received. The history of his lawyer patient ought to be republished and read by every physician in the world; for perhaps, every physician living has had, has now, or will have, just such cases; and without the correct knowledge obtainable from Dr. M's. account of this case, such patients would go on suffering in their vocations, or be driven by their pains from their chosen professions. Medicines will never cure such patients, nor can residence by the sea, combined with rest from labor, do more than give temporary relief. There is but one cure, and that is properly fitted glasses. The headache (not sick headache) from which Dr. M's. patient suffered so much was dependent on compound hypermetropic astigmatism, which was corrected by proper glasses, fitted by Dr. Thomson, of Philadelphia, a perfect and permanent cure resulting.

Dr. Mitchell gives the histories of other cases, in his February notes, which I believe would read differently had he sent them also to Dr. T., for no doubt (judging from the histories given) errors of refraction predisposed them to, and near work excited, their attacks of headache (not sick headache). I have had similar cases, to whom, only a few years ago, I would have administered bromide of potassium, and directed out-door exercise and freedom from close work, in whom I found hypermetropia or astigmatism, the correction of which with a properly fitted glass, cured them speedily and thoroughly. In every one of my cases among school children who complained of terrible headache on close application, the causing hypermetropia was latent and became manifest only after the use of a 1 per cent. solution of atropia in the eyes. I have the records of several such cases, but will briefly note only two of them. No. 1, a boy, aged 12 years. During vacation he has always been free from headache, and up to the time he entered school he had suffered none from headache. Always within two or three days after entering school his headache would come on; and as long as he continued in school his headache would continue—never a day of freedom from it. A vacation of only a few days would bring relief which would continue until school duties had been resumed. The boy's not complaining when he had nothing to do but to play, almost made his parents believe that his complaint when studying was assumed. When his father consulted me about him he said "I wish you would examine my boy and see if you can find any cause for his headache that seems to torment him so. Always when we start him to school he begins to complain, and sometimes we are forced to stop him." The history I gathered from the boy and his mother led me to believe that the cause of his malady was some error of refraction. I tested his vision and found it in each eye equal to $\frac{20}{xx}$, *i.e.*, at a distance of 20 feet he could call letters made to be seen at that distance. Apparently he had perfect sight; but it was only made so by continuous tension of the ciliary muscles, for, on paralyzing these with atropia, I found his vision for right eye $= \frac{15}{cc}$ and vision for left eye $= \frac{12}{cc}$. A + 16 was given him for O.D. and a + 14 for O.S., these glasses correcting in full the existing errors of refraction. His headache vanished, and he is now able to study as hard and as long as any one, without the least inconvenience. He is no longer a dull boy. His cure was instantaneous and complete. To see well when the axes of his eyes were parallel he had to strain almost as much as a person with perfect eyes would have to strain when the axis of his eyes converged to a point 12 inches from him; so we see that my patient had to doubly strain to read. His was not sick headache, but one of that class of headaches about which Dr. Mitchell so ably wrote.

No. 2 was a little girl, æt. 12 years: always harassed by headache of greater or less severity, according to application when in school. She came to me, July 4th 1881, for relief. To her I was able to make the declaration that henceforth she would be independent of headache; for I expected to fit her with glasses that would bring her relief. Her vision for right eye, ciliary muscle active, was $= \frac{20}{xxx}$, astigmatism causing the manifest defect; while her vision for left eye was $= \frac{20}{xx}$. After paralyzing her ciliary muscles and dilating her pupils, I found the vision of right eye $= \frac{10}{cc}$, and that of the left eye $= \frac{5}{cc}$. A + 10 gave her vision for left eye $= \frac{20}{xx}$, and a + 12 ⊃ + 60 cyl. ax. 75°, gave her vision for right $= \frac{20}{xx}$. These glasses she has been wearing, for near work only since she was fitted, and she has been perfectly free from headache during the whole time. Her history, before she was fitted with glasses was very like that of case No. 1. Rest from school duties would have given her temporary relief, and bromide of potassium would have lessened her suffering for a time, but the only thing that could ever have given her perfect immunity was a full correction of the errors of refraction in her eyes. Only two nights since she said to me "I would not take the world for my glasses and be compelled to do without them."

I could multiply notes of cases of headache like the above, all corresponding to the cases noted by Dr. Mitchell in 1874 and 1875, but I will close this article by giving the history of one case of *sick headache*, a malady different from *nervous headache*, so-called, though dependent on the same causes, and so common that a history of an attack need not here be given.

SICK HEADACHE.

The patient whose history I am about to relate, in support of my theory for sick headache, published in the REPORTER, July 29th, 1882, had her eyes refracted by me about eight months ago, without any knowledge on my part that she had ever had an attack of sick headache, and without her ever having thought that her severe and frequent attacks of sick headache in any way depended on the condition of her eyes. She had just passed through an attack of typhoid fever, and had been so reduced by the fever that her ciliary muscles could act but feebly, even after she had been convalescent some weeks. While convalescing her vision was $= \frac{20}{xxx}$, and at times not even that good; but when well, the power of the ciliary muscles having been fully restored, her vision was $= \frac{20}{xx}$. She stated to me, however, that it now tired her much more to read than formerly, and that my statement, made to her while she was convalescing, viz., that she was far-sighted, was, perhaps, true. She had me to examine her eyes, under the influence of atropia, when I found the vision of her right eye $= \frac{20}{lxx}$, and that of her left eye $= \frac{20}{c}$. Her latent hypermetropia had been made manifest by the use of atropia. A + 42 gave her perfect vssion in her right eye, and a + 36 brought about the same desirable result in the left eye. After getting her glasses she wore them constantly until about four weeks ago, when she had the misfortune to break them. The comfort she had derived from their use had been so great, she wrote me, saying, "I am lost without my glasses, so please get me new ones as soon as possible." I went about complying with her request, still ignorant that she had ever been a sufferer from sick headache. My opticians in Philadelphia had to shape the lenses to fit her frames, so that about ten days passed by before she received her new glasses. In this short interval, though she used her eyes as little as she well could, she had a very severe attack of sick headache, an attack of which she herself declares she had not had during the whole time she had worn her glasses. She further stated to me, only a few days ago, that before I refracted her eyes she had an attack of sick headache almost every week of her life. Her relief is certainly a propter hoc and not a post hoc. This case is a strong link in the chain of evidence which will soon place my theory beyond doubt. I have other links in preparation, and will soon add them to the chain.

Again, I earnestly solicit the observations of others.

HOSPITAL REPORTS.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINICAL LECTURE BY FRANCIS DELAFIELD, M.D., Adjunct Professor of Pathology and Practical Medicine.

Bright's Disease.

GENTLEMEN:—This is a man thirty-five years old, a boatman by occupation, who was admitted to the hospital two months ago. He says that in the course of his occupation he has been a good deal exposed to cold and wet, but he always had good health until two years ago.

Then, after taking cold, he had œdema of the feet and legs, and he noticed also that he passed a large amount of urine frequently. He had no vomiting, no headache, no disturbance of vision. This first attack of œdema of the legs lasted five weeks, and it incapacitated him from work. This condition gradually disappeared, and be-

tween this time and two weeks before his admission to the hospital he was perfectly well. Although two weeks before his admission he was perfectly well, still he was passing a large amount of urine. Then he took cold, and had another attack of œdema of the legs and feet, and this time the legs and feet reached a large size. The scrotum also was swollen, and he had an attack of acute bronchitis. When he was admitted to the hospital he was passing over 100 ounces of urine in the twenty-four hours, without any diuretic. The specific gravity of the urine was 1.015; it contained albumen and a few hyaline casts. There were no other symptoms. Since his admission, two months ago, he has gradually been improving, though there is still some œdema of the feet and legs, and he is constantly passing a considerable amount of urine—about 100 ounces in the twenty-four hours. The specific gravity is now 1.027. At the last examination there was no albumen or casts present. Here is a specimen of the urine which he passed during the past twenty-four hours. You will observe that the color is not perfectly normal, that it has not the clear, well-marked color of normal urine.

On looking at the man you see that he does not look badly. There is hardly any œdema of the feet and legs at the present time. The heart's impulse is somewhat diffused, so that it is difficult to place the apex. It is displaced a little to the left, as I judge from the stethoscope. There is no murmur. The patient says he has had constitutional syphilis.

That is the history of the case. Of course, many of you would say the man has chronic Bright's disease, or chronic diffuse nephritis; but the question is, what particular variety of chronic diffuse nephritis has he? I hear some one say "atrophic kidney." There is a good deal to be said in favor of its being atrophy of the kidneys. The large amount of urine that he is passing, the long continuance of the disease, the hypertrophy of the left ventricle, all of them point to the existence of atrophic kidney. But those are not the only elements in the case. The amount of urine that he is passing—over 100 ounces every day—is rather large, even for atrophic kidneys to pass a long while. Patients with atrophic kidneys will pass that amount for some time, but it is a good deal for them to pass all the time. Then, besides, you will observe that the one symptom which he has had besides the change in the urine is œdema of the legs. Now, dropsy is one of the least frequent symptoms that belong to atrophic kidneys. I do not mean that there are not plenty of cases of atrophic kidneys in which there is dropsy, but usually it is not the only symptom. If the patient has atrophic kidneys and has dropsy he will usually have some other symptoms besides. It is not often you have dropsy as the first and only symptom. And you will observe that that one symptom has troubled this man, and nothing else. Then, besides that, we cannot neglect the fact that the man has suffered from constitutional syphilis. So that, although it is possible that he has had atrophic kidneys, yet I think there is something else which may also suggest itself as being perhaps more probable.

"The large white kidney." If you should simply say the large white kidney, it would hardly apply. "The large white kidney of the diffuse variety." You mean chronic diffuse nephritis, and the large white variety; that would not apply in general. That is, the ordinary examples of the large white kidney would not give you such a history. But there is one particular form of the large white kidney which might give such a history; that is, the so-called waxy or amyloid kidney; that form of chronic diffuse nephritis in which the gross appearance of the organ is that of the large white kidney, and in which the tufts of the malpighian bodies and the walls of the blood-vessels are infiltrated with the so-called amyloid or waxy material. There is no absolute certainty, but the probabilities are that in this case the diagnosis would lie between these two conditions, between the simply atrophic kidney and the so called waxy kidney.

But here, again, there comes in another element of uncertainty, and that is, that it is perfectly possible, although it is not very common, for a patient to have, at the same time, the atrophic kidney and the waxy kidney. All the waxy kidneys are not of the large, white variety. A man may have a kidney which has the ordinary appearance of the atrophic kidney, and the blood vessels may be the seat of waxy infiltration, and when that is the case you will get a history a good deal like the history of this man. The probabilities are that this man is suffering from one or the other forms of waxy kidney; that he has either the large white kidney with waxy infiltration of the arteries, or the simple atrophied kidney with waxy infiltration of the arteries. There is one part of his history, however, which does not belong properly to the waxy kidney at all, that is, the high specific gravity of the urine. You will observe that its specific gravity is between 1.015 and 1.027, the latter being the specific gravity at present, although he is passing 100 ounces daily. That is certainly not characteristic of either the large white kidney or the atrophied kidney, or of any of the forms of waxy kidney. But in spite of that, I think we will have to accept this high specific gravity as an accident in this particular case, and not be influenced by it in making a diagnosis of the disease.

Now as to the prognosis and treatment. The treatment is, practically, the being quiet in the hospital and getting better. The man has been improving since he came in; he will probably soon be well enough to go out and attend to his business again; how long it will be before he will have another attack we can hardly tell, probably not as long as the interval between the first and the second attack; it is hardly probable he will again go two years without another attack; probably next fall the œdema will again return. I do not know that there is any special advantage which can be gained by his following out any treatment during the interval. He will, of course, protect himself against exposure to cold and wet; he should avoid the habitual use of alcohol; he should take as good care of himself as he can, with the idea of putting off a recurrence of the attack as long as possible, but a recurrence at some time

or other is pretty sure to come. I should rather hope, in his particular case, that he would escape until next fall, but it is very likely that we shall at that time see him again.

Case 2.—This patient is a man, thirty-two years old, who was admitted to the hospital over two weeks ago. The history was, that three months before the time when he was admitted he noticed that his feet and legs were becoming œdematous, and that at the same time he had ascites, the dropsy of the peritoneum coming first, and that of the legs and feet coming afterward. This dropsy has continued up to the present time. He has been tapped three different times. He passed his urine frequently and in small quantities. He has had no headache, and he denies having used alcoholic liquors. At the time when he was admitted there was a good deal of ascites, and there was œdema of the legs, feet and scrotum. The heart was pushed up by the fluid, as was also the liver. The specific gravity of the urine was 1.016, it contained albumen, and epithelial and granular casts. The man suffered a good deal from dyspnœa, apparently due to the pressure of the fluid. After his admission to the hospital the urine was passed in quantities from 45 to 15 ounces, and for some time lately the daily quantity has been small, from 20 to 15 ounces.

Two weeks ago his abdomen was tapped and 545 ounces of serum were drawn off. The dyspnœa, the nausea and vomiting which he was suffering from before the tapping, were relieved, and the amount of urine excreted was then increased. He did pretty well for several days, when the fluid began to reaccumulate, and the amount of urine passed during the twenty-four hours began to decrease, and so he has been going on, up to the present time. Yesterday his urine was of a specific gravity of 1.016; it contained albumen, granular and hyaline casts, and in quantity about twelve ounces. He was well until three months before coming into the hospital.

On looking at the abdomen, you notice that it is swollen, and that the cutaneous veins are distinctly increased in size. When we tap the abdomen with the finger we get the characteristic wave of fluid without any trouble. There is flatness on percussion as high up as the third rib on the right side. This, of course, means that the liver is pushed up by the fluid; that shows that the yielding of the diaphragm in this particular case has been greater than the yielding of the abdominal walls. You will find a difference in this respect in different cases of ascites. In some cases of ascites the abdominal walls yield to the pressure of the fluid a good deal, and the diaphragm yields comparatively little; in others the yielding of the abdominal walls is not as marked, and the diaphragm yields a good deal, being pushed upward into the thoracic cavity. This is evidently the case with this man. The abdomen is very tender; I presume he has some chronic peritonitis, and it is not worth while to distress the man in trying to feel the lower edge of the liver. There is very little doubt but what it is above the free border of the rib. I presume that it is a small liver pushed upward. The splenic dullness I cannot make out, because the liver and intestines are pushed up over the region where the spleen should be, and besides that the man is exceedingly sensitive.

We have, then, at the present time, marked ascites, tenderness over the whole of the abdomen, the liver pushed away upward, and you will observe, from the appearance of the man's face, that his general nutrition has suffered very much. He is very much emaciated; his whole condition is exceedingly bad.

Well, that makes up the history of the patient, and the question is, what disease or diseases is he suffering from? "Cirrhosis of the liver." I think there is no question but what he is suffering from cirrhosis of the liver. What else? He has some kidney trouble in addition to his liver trouble; now, what is it? "Cirrhotic kidney." Yes, the so-called cirrhotic kidney; the atrophic form of chronic diffuse nephritis.

You observe that the cirrhosis of the liver in his case is giving trouble in two ways: In the first place, it is producing dropsy to a very marked extent. He has a great deal of fluid in his abdominal cavity. The dropsy in his case is a very prominent feature, and a very serious feature, but in addition to the dropsy you will observe the man's appearance; look at the color of his face and the emaciation of the face and neck. All this is hardly to be explained either by the dropsy or the complicating chronic diffuse nephritis. How can we explain it? "By the presence of chronic gastritis." The only evidence we have of chronic gastritis is nausea and vomiting, and the fact that chronic gastritis is very common with cirrhosis of the liver. But you will observe that the nausea and vomiting in his case seem to depend more upon the pressure of the fluid than upon the condition of the stomach. After he has been tapped the nausea and vomiting are very much better, and they return again after the fluid reaccumulates. Chronic gastritis alone ought not to make such a looking patient as we have here.

"Functional disease of the liver." Yes; that the cirrhosis, in addition to producing dropsy by mechanical pressure upon the portal vein, has caused a change in the substance of the liver, which has so interfered with its functions that the man's whole nutrition has suffered in this way. That is the ordinary explanation of this condition, and I think it is sufficient, here, that the man's whole nutrition has been suffering, and is suffering now to a very great extent, because the liver ceases to perform the functions of the normal liver. It is impossible for the nutritive processes to be carried on properly unless the liver is performing its function properly; and there are a considerable number of cases of cirrhosis of the liver in which, in addition to the dropsy, we have this disturbance of the functions of the liver very marked, and when that is the case we get just such a looking patient as you see here—patients who look almost as if they were suffering from malignant disease.

I forgot to show you his urine. You will now observe that it is higher colored than it should be; that it looks as if it had blood in it, but the microscopical examination shows no blood, nor do chemical tests show the presence of any biliary

coloring matter, so that I presume the color is due to the presence of the coloring matter of the blood, without the existence of any blood corpuscles. We sometimes do have urine colored in this way.

Case 3.—Here is a boy twenty-two years old, who was admitted to the hospital nearly a month ago. He had been sick three months before he was admitted to the hospital, and the first symptom which he noticed was dropsy of the feet and legs. The dropsy extended up from the feet and legs, and became general. At first the urine was diminished in amount, but afterward the quantity increased and continued at about the normal. He has had no headache, no disturbance of vision. When he was admitted to the hospital he was still suffering from general anasarca. There was no headache, no vomiting. He was passing twelve ounces of urine in the twenty-four hours, of a specific gravity of 1.026; it contained fifty per cent. of albumen, and also granular and epithelial casts.

The patient was put upon the use of warm baths every second day, and under this treatment his urine increased in amount up to from 50 to 80 ounces. He was also taking a diuretic in addition to the general bath, and the dropsy steadily diminished.

The patient was doing well and passing large amounts of urine until four days ago, when the dropsy began to return and has continued up to the present time. The urine again diminished in amount, the hot water baths were resumed, but the œdema increased somewhat again. Yesterday he passed about twenty-eight ounces of urine. Bitartrate of potash was the diuretic given.

Here you have a very straight-forward history indeed; a much plainer case than either of the other two cases which you have seen. You have a young man who dates his whole trouble back about four months ago, and the first thing that he noticed was that he was becoming dropsical, that there was œdema of the feet and legs, and that he was passing less urine than he should. The dropsy continued up to the time of his admission into the hospital, about three months, and it still existed as well marked general anasarca. At that time he was passing only about twelve ounces of urine daily, of specific gravity of 1.026, and containing 50 per cent. of albumen, and also containing granular and epithelial casts. As an effect of treatment the urine was increased very much in amount, so that now, instead of passing twelve ounces in the twenty-four hours he passes over one hundred ounces, and the dropsy then decreased. But he still has considerable dropsy, and the increase in the flow of urine is no longer having the effect to reduce the amount of dropsy, which it should have. Except for the dropsy, there have been no symptoms; the man has had no disturbance of the stomach, his color is fairly good, his lips are almost as red as they ought to be; I think there is no heart trouble. There is, however, a not very loud murmur at the base of the heart with the first sound, which is probably a blood murmur. The heart is not increased in size.

Now, as said, there is a very straightforward history of disease of the kidney of some kind. "The large white kidney." Yes, that particular variety of chronic diffuse nephritis. You could hardly have a more straightforward history of a case of that particular form of chronic diffuse nephritis. It is characteristic in every respect.

Now, as to the prognosis and the indications for treatment. With regard to the latter, the one indication is to get rid of the dropsy. The dropsy is the one thing that troubles him. You will observe that, at first, increasing the amount of urine had its proper effect upon the dropsy; that the dropsy diminished while the urine increased. But at the present time this effect has ceased; he passes nearly double the amount of urine that he ought to pass, and yet the dropsy has persisted, so that evidently we are not affecting the dropsy in this way. The use of the hot baths and the diuretics which should increase the flow of the urine are not getting rid of the dropsy. When a patient behaves in this way, and when he is still in as good condition as this young man is in, the indications are usually to stop the use of the diuretics and to use iron in some shape or other, for when you find that increasing the amount of urine has no effect upon the existence of the dropsy, it is evidence enough that there is no particular use of going on stimulating the kidneys and making them constantly pass more water than normal, when the dropsy continues, or increases just as it did before. So that while you may well enough continue your attention to the skin, continue the hot water or hot air baths. It is better at once to stop the internal diuretics and to commence with one or the other preparations of iron. If the case is not of very long duration, as is the case with this young man, you will often get good enough results from these means. If it was an older case, if this boy had been sick a year, or two years, instead of three months, then I should think it made very little difference what you gave him. These older cases of the large white kidney, when they exhibit the particular combination of an increased amount of urine with increasing dropsy, go on to do badly, no matter what you do. You can take this as a pretty good general rule, that in a case of large white kidney, over a year old, in which the patient has the combination of an increased amount of urine with increasing dropsy, the patient will not get better, but will continue to get steadily worse. But in the early period of the disease, when the symptoms have existed only a few months, then the condition of things is not as bad, and it will be possible enough for this young man still to get better, although he has this combination of dropsy and a large amount of urine.

The Absurdity of Anti-Vivisection.

The absurdity of the English law against vivisection is well illustrated by a remark of Sir James Paget. He says, "I may pay a rat-catcher to destroy all the rats in my house with any poison he pleases, but I may not myself, unless with a license from the Home Secretary, poison them with snake-poison."

Aneurism of Carotid—Ligature—Recovery.

Mr. Stanley Boyd reports the following case in the *Medical Times and Gazette*:—

J. De V., aged twenty-eight, was admitted on July 29th, 1876. The history he gave was as follows: During the month of February, 1876, he noticed a swelling on the right side of his neck, and becoming alarmed, he applied for relief to a woman living in St. Helier. For five weeks he continued under her care, the swelling steadily increasing. She treated him with "herb medicines," and gave him a plaster, which he wore for a month. No good resulting from these remedies, he next placed himself in the hands of a "charmer" residing at St. Ouen's, and every morning for seven weeks he drove nine miles into the country to see this man, who contented himself with simply touching the swelling. Finally, on July 29th, he entered the General Hospital, under the care of Mr. Charles Godfray.

At the time of admission the swelling was of large size, extending from between the angle of the jaw and the mastoid process to about an inch and a half above the sterno-clavicular articulation. The pulsation and bruit were plainly marked, and the aneurism showed a strong tendency to burst at the hinder part, where the skin was thinner than elsewhere, and of a claret color. The larynx and trachea were pushed far over to the left side. Swallowing, even of liquids, which for some time had been attended with great difficulty, now became impossible. Large nodes on the tibiæ, first noticed shortly before Christmas, revealed a syphilitic taint.

On July 30th, Mr. Godfray applied a silk ligature to the common carotid, close above the sterno-clavicular articulation, and considerable decrease immediately took place; but unfortunately the size of the neck was not taken until August 3d, when it was seventeen inches at the widest part, the patient being a very spare man. The ligature came away on the twelfth day (August 11) after the operation.

The tumor decreased slowly but steadily until about August 27th, when it began to increase rapidly, and in two or three days a fluid swelling had run upward to the ramus of the jaw and forward to the chin. Inability to swallow returned, and the larynx was again thrust over to the left side.

On the evening of the 30th violent hemorrhage occurred. About a pint of blood seemed to have been lost, but as the bleeding stopped before the head nurse—who was in the next ward at the time—could reach the room, it was not noticed whether the blood came from the proximal or distal end; it was, however, of a dark color. The swelling continued as large as ever; no pulsation or bruit could be detected in it. Any attempt to swallow, even the smallest quantity of fluid, occasioned violent coughing, which caused its return by mouth and nose.

On September 1st and 2d small injections of beef-tea were given, but they were retained for a short time only. On the afternoon of the 2d, Mr. Godfray passed a small-sized stomach-tube with less difficulty than had been anticipated, and the patient was fed with beef tea. On the same evening, eggs beaten up in milk were similarly given.

On the morning of the 3d the swelling had not decreased in size, neither had it become more solid. It showed strong signs of pointing at the hinder part. A needle, connected with an aspirator, was passed into it at this spot, and nine ounces of foul-smelling, dark colored blood were drawn off. The flaccid parts were kept in contact by strips of plaster. The patient felt much relieved by this operation, and on the following day he was able to swallow milk and eggs, mouthful by mouthful, but still with some difficulty. On the 4th and 5th the sac filled slightly with fluid from the surrounding parts.

On the evening of the 5th, after a fit of coughing, the sac burst into the pharynx, and a quantity of blood and mucus was coughed up, the sac being completely emptied. Great relief followed, and the larynx returned to the middle line. The patient now swallowed with much greater ease, the walls of the sac rapidly adhered, and he was discharged, well, on September 11.

September, 1882.—The patient is now in good health.

A Simple Operation for Varicocele

In the *Lancet*, Dr. Arthur E. Barker says:—

Having three cases to operate on last autumn, I dealt with them as follows: two on one day, the other five days later. The skin of the scrotum was thoroughly cleansed with a five per cent. carbolic lotion, as also all instruments and the surgeon's hands, no spray being used. The scrotum was then pinched up between finger and thumb, in the usual way, so as to include the veins and exclude the vas deferens; it was then notched with a scalpel, and through the opening thus made a needle bearing a medium-sized twisted silk ligature (previously soaked for about an hour in the same carbolic solution) was passed. The veins were then allowed to slip backward, and the needle was made to carry the silk forward again, through the same puncture, but this time in front of the veins. The latter was thus, of course, included in the two loops of silk leaving the scrotum by the same aperture. The ends of these were now tied tightly over the veins, about one-eighth of an inch apart. They were then cut short and allowed to slip into the scrotal tissues. Everything was in the meantime protected from any contamination by frequent wiping with a carbolized sponge. A little padding of salicylated wool was the only dressing.

The results need only be briefly alluded to. There was a very trifling swelling around the seat of ligature for a few days, together with slight tenderness on pressure, otherwise nothing

was complained of in the first two cases. In the third, considerable pain was felt for a day or two, and there was a little more swelling and tenderness. But in none of the three cases was there the slightest threatening of suppuration. The first left the house in ten days, the second within a fortnight, the last on the fourteenth day. They were then walking about without any discomfort, except the third, who, having had a very large varicocele, still felt a good deal of dragging in the loins on returning to his work, which was very hard, and some neuralgic pains. These, however, passed off later, under the use of laxatives, for obstinate constipation, from which he suffered, though he continued to work for long hours as a grocer's assistant. I watched all these three cases for several months, the last until quite recently, about a year after operation, and now regard all danger of the ligatures coming away as quite over. The latter could be felt under the finger as small knots, deep in the scrotal tissues, which appeared quite normal. Whether they will ever come away remains to be seen, but this is immaterial, as far as the patient is concerned, for they give no trouble now.

Comparing these operations, as far as they go, with the older methods, their extreme simplicity is worth noting, as well as the small amount of trouble or inconvenience to the patient. It is also of some interest to note that, in these three cases, at all events, it was possible to manipulate freely with silk ligatures, and yet introduce them in a sufficiently pure state to produce no suppuration of any kind; and all this with only the simplest precautions as to absolute cleanliness, and without the carbolic spray. There is also a satisfaction in knowing that the veins are thoroughly occluded, and that there is no possibility of the ligatures slipping or being too soon absorbed, as might be the case with catgut. If nothing else, the operation appears an interesting experiment, and worthy of further trial.

The Rational Treatment of Menorrhagia.

Dr. Arthur W. Edis read a paper on this subject, in the Section of Obstetric Medicine, at the last meeting of the British Medical Association, (*Brit. Med. Jour.*,) from which we extract the following. In the term *menorrhagia*, he includes all cases of uterine hemorrhage occurring in the practice of the gynecologist, whether as profuse or prolonged menstruation, or as a loss of blood from the uterus other than that which occurs at or about the time of parturition. Sometimes it acts as a safety valve, a smart attack of hemorrhage often serving to avert a still more serious effusion from the ovary, or its surrounding plexus into the peritoneal cavity, or even preventing an attack of apoplexy at the so-called climacteric period. Diagnosis is the most important element of treatment, for menorrhagia is merely a symptom, not a disease. The age of the patient will often give us a clue to the cause; cardiac complications from rheumatic fever, hæmatocele, ovarian irritation, constipation, etc., in the young; polypi, fibroids, retroflexion, retained products of conception, in the middle aged; climacteric irregularities, cancer in its various forms, hepatic disorders etc., between the ages of forty and fifty. In young plethoric girls, when menstruation is profuse, instead of iron, which will increase the trouble, regulate the diet, limit animal food and use bromides, to lessen ovarian irritation, along with an occasional saline aperient. In anæmic patients, when iron is used it should be combined with salines in moderate doses, as a chalybeate water. In single patients, where menorrhagia is marked and persists in spite of general treatment, an examination should be insisted upon. When the slightest irregularity in the appearance of the catamenia leads to the suggestion of the possibility of pregnancy, any attack of menorrhagia, and especially if it recur, should be regarded as a threatened miscarriage and treated accordingly. When uterine hemorrhage is severe, whether from imperfect expulsion of an early ovum, intra-uterine polypus, submucous fibroid tumor, or other similar conditions, in place of attempting to restrain the flow by linen or cotton packed in the vagina, a far more rational and scientific method will be to insert a sponge tent into the cervix uteri. This will ckeck the hemorrhage and dilate the cervix to facilitate subsequent examination. Hæmatocele is a frequently overlooked cause of menorrhagia, as is also extra-uterine gestation at an early stage.

If hemorrhage be severe and continuous, and the probability of extra-uterine gestation exist, the patient's life being evidently jeopardized by the amount of effused blood withdrawn from the circulatory system, the only hope of saving the patient is to make an exploratory abdominal incision, secure, if possible, the bleeding vessel, or remove the ruptured cyst, as may be found advisable.

Retroflexion, accompanied by congestion of the uterus, in patients who have borne children, is not an unfrequent cause of menorrhagia. A correct diagnosis is here essential before treatment is likely to prove of service. The two conditions are often so intimately associated that, unless both of them be dealt with simultaneously, permanent relief is not obtained. The misplacement serves to keep up the congestion, and the latter equally tends to prevent the uterus from assuming its normal position. Puncturing, scarification, or the application of leeches, followed up by hot water injection and glycerine plugs, may first be tried, to lessen the congestion, a ring pessary, or other appropriate support, being then inserted, to keep the uterus in its normal position, and thus lessen the tendency to a recurrence of the congestion.

The management of hemorrhage, due to large intramural or submucoid fibroids, is one often of much difficulty. Where ergot, bromides, cannabis indica, gallic acid, digitalis, and other similar remedies, fail to arrest the flow, and the patient's health is markedly affected by the repeated or severe losses, the question of spaying, division of the cervix uteri, or removal either of the fibroid or of the entire uterus, should certainly be entertained. The results obtained during the last few years by operative interference in these cases are most encouraging, and the operation well deserves more extended trial. No patient, the subject of uterine

fibroid, where the symptoms are so severe as to impair her usefulness or threaten her life, should be allowed to die unrelieved, without having the option of operative interference.

Vascular disturbances at the climacteric, or change of life, as it is popularly spoken of, should never be treated lightly, but always carefully investigated.

In some instances, regulation of the bowels, restriction as to diet, especially the amount of alcohol, and a proper amount of out door exercise, will be all that is requisite. In others, the hemorrhage persists, in spite of all treatment, and, on a careful investigation, epithelioma of the cervix uteri is at once detected, probably too late for any operative interference. In no case should hemorrhage at this period be diagnosed as change of life, without a careful examination being made and a correct diagnosis formed.

In cases of epithelioma of the cervix, when hemorrhage is a marked symptom, in place of giving ergot or iron and plugging the vagina, it will be much more rational to remove as much of the diseased mass as may be deemed prudent, with the écraseur or curette, or both combined, and then to apply either the liquor ferri perchloridi fortior, the persulphate of iron or the actual cautery.

Device for Estimating Hæmoglobin.

Dr. Charles Finlay, in the *Lancet*, says the following device for estimating the amount of O. hæmoglobin contained in a small quantity (say five cubic millimeters) of human blood will perhaps be acceptable to some of your readers who, like myself, have to work at a distance from reliable instrument makers, and might induce some of the latter to supply the profession with the necessary apparatus.

The principle of my contrivance is not new, being an application of Preyer's spectral estimates of hæmoglobin solutions, and of a tube similar to those employed by Dubosq, in his calorimeter, so as to compare successive measurable depths of a blood solution. The novelty, if such there be, consists in the use of a diluted solution of blood obtained from any red-blooded animal, as a gauge determining the depth of this solution, that will give one or other of Preyer's O. hæmoglobin spectra, and observing the difference of depth required to obtain the same spectra, after a cell, one centimetre deep and filled with one per cent. solution of human blood, has been introduced under the gauged animal blood.

I had only at my disposal a small Browning's pocket spectroscope, of the simplest pattern. I mounted it as an eye-piece, suited to my microscope, and fitted to its distal end, beyond the slit, a hard rubber tube, about twelve millimeters in diameter. The lower end of this tube was cut perpendicularly to its axis, and closed with a plain glass disc, well cemented around the edges. When this eye-piece is in position, and the sliding tube of the microscope is pushed home, the glass plate of the rubber tube touches another glass plate which forms the bottom of a cylindrical vessel standing upon the stage of the microscope. Into this vessel I introduce about fifteen cubic centimeters of a dilute solution of defibrinated blood (the requisite quantity, less than one cubic centimeter, being easily obtained by pricking, for instance, a vein under a chicken's wing), and graduate the solution so that from twenty-five to thirty millimeters of depth are required in order to produce the particular spectrum selected as a type, and the value of which in O. hæmoglobin percentage should be especially determined for each particular instrument. The depth is, of course, measured by the distance between the two glass plates already mentioned, but it can be read off at once, provided the sliding tube of the microscope has been ruled on the outside with lines one millimeter apart, and numbered from above downward. The exact depth that produces the typical spectrum having been noted down, the instrument is ready for immediate use.

A cell formed of a piece of hard rubber syringe, No. 0 (say half centimeter, inner diameter), exactly one centimeter long and cemented upright to a microscope slide, is now filled with a mixture of five cubic millimeters of human blood in 500 (half cubic centimeter) of distilled water, and covered with a thin glass cover, excluding all air-bubbles. This cell is introduced between the stage and the glass bottom of the cylindrical vessel containing the diluted chicken's blood, and the typical spectrum again sought for. It will, of course, be found that a lesser depth is now required than before the addition of the centimeter cell with the human blood, the difference between the two depths, divided by the full depths previously noted down, multiplied by the percentage of O. hæmoglobin corresponding to the typical spectrum, and finally multiplied by 100, will be the percentage of hæmoglobin contained in the pure human blood from which the sample was taken.

Apomorphia—Morphia.

Muriate of apomorphia is a remedy which, in our country, has by no means come into such general use as yet, as the well-known effect of this remedy would seem to justify. In an article on cough and expectoration, * Prof. M. J. Rossbach gives the following report of his investigations regarding the effect of morphia in combination with apomorphia.

His results, gained from experiments on animals, as well as from clinical and general practice, have been extraordinarily favorable. Concerning the action of these drugs, his own words are as follows:—

1. Muriate of apomorphia can, alone and internally, without hesitation, be administered as an expectorant, in single doses of 0.005–0.01 ($\frac{1}{12}$ to $\frac{1}{6}$ grain); a dose of 0.03 ($\frac{1}{2}$ grain) *per diem*, in children and adults, sufficed to change an annoying and dry, frequent cough, into one rare, moist and not annoying, accompanied by easy expectoration; frequently much less, only occasionally, more is necessary. R. increased the *daily* dose up to one grain; it is, as a general rule, best to commence, in all cases, with a daily dose of half a grain, subdivided into four or six

* Sep. *Abd. Berl. Klin. Wochschrift*, 19, 20, '82 ref. *Deut. Med. Zeit.*, Aug. 17, '82.

doses, according to age and the nature of the case and the effect of the drug; this dose is then either diminished or increased. Vomiting, which occasionally will happen when a larger dose is given, even one usually not considered an emetic dose, does no harm. Subcutaneously, doses of $\frac{1}{100}$ to $\frac{1}{6}$ of a grain (through central influence) prove frequently emetic. The apomorphia seems also, in phthisical persons, to be a valuable substitute for morphia. This remedy (apomorphia) and emetics (ipecacuanha) and pilocarpia, he considers the expectorants *κφτ'ἐξοχήν*, and these are the only ones he ever employs, as their action is sure and reliable.

According to R's experience, the following are the best methods of administering apomorphia:—

℞. Apomorphiæ muriatis, gr.ss–gr.$\frac{5}{6}$
Acidi muriat. diluti, ♏viij
Aquæ destillatæ, f℥v. M.
D. in vitro nigro (in dark bottle).
Sig.—A tablespoonful every two hours.

2. The combination of apomorphia with morphia causes a diminution in the frequency of the cough, and makes the expectorated matter more fluid.

℞. Morphiæ muriatis, gr.ss
Apomorphiæ muriat., gr.ss to gr.j
Acid hydrochloric dilut., ♏viij
Aquæ destillatæ, f℥v. M.
D. in vitro nigro.
Sig.—A tablespoonful every two to four hours.

3. In certain cases the addition of atropia is highly recommended by R., but he is totally opposed to giving the latter together with the above medicine, *i. e.* in one and the same mixture, and prefers the following mode of administering all three remedies:—

℞. Morphiæ muriatis, gr.$\frac{1}{3}$ to gr.j
Apomorphiæ muriat., gr.ss to gr.j
Aquæ destillat., f℥iv
Syrup rubi idaei, (raspberry syrup), f℥j. M.
Sig.—A tablespoonful every two to four hours.

℞. Atropiæ sulphatis, gr.$\frac{1}{80}$.
Pulv. glycyrrh,
Succ. glycyrrhiz., āā q.s.
Fiat pilula, dentur tales, No. xx.
Sig.—One or two pills to be taken at night.

The first solution is given during the day; the pills are best administered in the evening, between 6 and 10 o'clock; one every two hours, with one or two tablespoonfuls of the mixture at the same time, if the frequent irritating cough should indicate such procedure. This treatment is especially recommended in cases of abundant secretion, but not in phthisical persons with a cavity.

Salicylic Acid in Typhoid Fever.

At a recent séance of the Académie, M. Vulpian, made a long and interesting communication on the treatment of typhoid fever by salicylic acid. He had already experimented in this disease with the salicylate of bismuth, carbolate of soda, and boracic acid. With large doses of the bismuth salt, he obtained a notable fall of the temperature, and an incontestible amelioration in the general condition of the patient. But the effect was not lasting, and when pulmonary complications supervened and the full dose of 12 grains could not be given, it was found that smaller doses did not have the same effect.

In this disease it does not suffice, to destroy the typogenons poison in the intestine alone, for it has been already absorbed into the system. It is then necessary to follow it up and attack it in the blood and tissues of the organism.

Carbolic acid is too toxic to be administered in large doses; M. Vulpian has given carbolate of soda in pill form in doses of 30 grains per diem, but without obtaining any well-marked effects. Boracic acid was given in doses of one-half ounce per diem, in a quart of tartaric lemonade, but here again the therapeutic action was almost nil. Salicylic acid has been used by many observers in typhoid fever. M. Vulpian first employed it rubbed up with phosphate of lime, then with sugar of milk, and finally alone. He administered about one drachm and a half of the pure acid per diem, giving from four to five grains every half hour. In most of the patients submitted to this treatment the temperature fell two or three degrees in from 48 to 72 hours, and there was a notable amelioration in the general condition of the patient.

In severe cases the action on the temperature was not so evident.

Salicylic acid does not appear to shorten the duration of the malady, and, as regards its influence in diminishing the proportion of deaths, the number of cases where it was used as an exclusive method of treatment are not sufficiently numerous, as yet, to express an opinion.

M. Vulpian does not, however, hesitate to affirm that no other medication produces so constantly a considerable fall of the temperature and so marked an amelioration in the general condition of the patient. He concludes that, while salicylic acid does not constitute a veritable curative agent, it yet has a powerful moderating influence on typhoid fever, and merits a prominent place in the ordinary treatment of this disease.

Extraordinary Case of Early Puberty.

Dr. T. Woods says, in the *Lancet*:—

The following case is, I think, worthy of being put on record: W. is now six years and seven months old, having been born on January 21st, 1876. A week or two ago I saw him while bathing, and was greatly surprised to see that his genital organs were as fully developed as in the adult, and his pubes covered with a thick crop of dark brown hair, presenting the appearance of a youth of seventeen or eighteen; hair is also commencing to grow on his upper lip. His height is about 4 feet 9 inches, and he is big and muscular in proportion, but I regret that I am unable to give his weight and chest measurement. His voice, for more than a year, has been gruff and hoarse, as it usually is at puberty, and his grandmother tells me that he has had hair on the pubes since he was three years of age. He is so wild and mischievous that she has had to apply to the magistrates to have him sent to an industrial school, which they consented to do, and he has now been committed for five

years. A few days ago he took away a tradesman's cart, upset it on the roadside, cut the harness into pieces, and galloped the horse about till he was tired of the fun, and then let it go. His clothes were taken away from him, and he was put to bed, to keep him from further mischief. He, however, managed to find his grandfather's best black trousers, cut off the bottoms, so that they might fit him, and escaped through the window. One day, recently, he found some pigs straying, and drove them some miles to a butcher, and tried to sell them; failing to do so, he gave them away to some one he met. It required three policemen to take him to the workhouse (to which he was sent until arrangements could be made for his removal to the industrial school), and when they had carried him there, face downward, as they were compelled to do, he smashed a bedstead into atoms, kicked the plaster off the walls, cursed and swore in a most fearful manner, and had to be removed to the police-station, for safety. He was not a large baby at birth, but grew rapidly after twelve months. He commenced to cut his permanent teeth between four and five years of age. His father is in a lunatic asylum, suffering from melancholia. I have known the child since birth, and am perfectly certain of his age.

Morphiomania.

The *Medical Times and Gazette* says that in a paper read at the Rochelle meeting (*Gaz. Hebd.*, September 2), Dr. Landowsky drew attention to the fact that, besides the cerebral disturbances caused by the excessive use of morphia, venous congestions were also induced by it, which in the long run led to permanent lesions, especially of the kidneys, inducing albuminuria or glycosuria. He also called attention to the too great frequency with which injections of this powerful agent are entrusted to inexperienced nurses and the patients themselves. Prof. Verneuil remarked upon the frequency with which patients who came to consult surgeons have before that time been trying and abusing the hypodermic method. In their case a condition is generated which, at the time they may have to undergo an operation, may compromise their existence by their intolerance of chloroform, or later on expose them to the occurrence of fatal erysipelas or diffuse phlegmon; not that they are still under the influence of morphia, but have become, through it, the subjects of glycosuria, albuminuria, etc. M. Rochard, in relation to the colossal doses that are sometimes employed, cited the case of a lady who injected as much as three grams (forty-five grains) of the hydrochlorate of morphia daily. He further remarked that even when large doses are injected, neither constipation, loss of appetite, nor any other affection of the digestive organs is produced, while even small doses taken into the stomach produce these effects. Dr. Landowsky has observed in several women who accustomed themselves to excessive injections, that small mucous bursæ formed on the sides of the first phalanx of the index and median finger, which are due to the manner in which these morphio-maniacs practice the injections rapidly, with one hand, when they are alone. In doubtful cases, the existence of these bursæ may throw light on the diagnosis.

Lesions of the Phrenic Nerves.

The *Lancet* says that the effects of lesions of the phrenic nerves have been studied experimentally by MM. Henocque and Eloy. The effects on respiration, of injury to one or both, were registered on recording apparatus. The immediate effect of a lesion of one nerve was found to be a change in the respiratory rhythm, the movements being at first rendered more energetic. After a few moments the diaphragm ceased to move on the side which had been injured, and the contractions of the inferior intercostal muscles and accessory elevators of the upper ribs were rendered feeble. The experiments were made on animals in which the respiration is both abdominal and costo-abdominal—the dog, cat, guinea pig, and the monkey. Death often rapidly follows an injury to the phrenic nerve, but some animals survive, and the thorax is then motionless on the corresponding side, especially in the cat and the monkey. The respiratory movements become visible a few days afterwards, and are of course due only to the intercostals. At a later period, during the reparation and regeneration of the nerves, the tone of the voice was observed to be altered. Respiratory tracings, taken two, four, and ten months afterwards showed the gradual return of the respiratory curve to the normal. But even when the rhythm was restored, the movements continued deficient in extent. Moreover, in spite of the regeneration of the nerves, there remained a hypertrophy of the inferior intercostal muscles, set up by their supplementary activity.

Reviews and Book Notices

BOOK NOTICES.

The Principles and Practice of Surgery. By John Ashhurst, Jr. M.D., etc. Third Edition, Enlarged and thoroughly revised; with 555 illustrations. Philadelphia: Henry C. Lea's Son & Co., 1882. 8vo, pp. 1064.

Dr. Ashhurst's *Surgery* has won more than an average share of professional esteem. It is a condensed treatise, covering the whole domain of the science in one manageable volume, and in these days of unwieldy, spread-out encyclopædias, it is a relief to many to find a writer whose aim is to say the most in the least compass.

The present edition has had a thorough revision, the novelties in surgical practice and the recent observations in surgical science have been incorporated, but the size of the volume has not been materially increased. The opportunities of the author as a clinical teacher and hospital surgeon, as well as his experience in a large private practice, have been of avail to him in deciding, from personal observation, the superiorities of the methods he recommends.

His arrangement is perspicuous, and his language correct and clear. The work is well printed, and an excellent index closes the work. On the whole, we consider it the best system of surgery in one volume which could be named as the product of an American author.

Microscopical Morphology of the Animal Body in Health and Disease. By C. Heitzmann, M.D. 1 vol., 8vo, pp. 849. J. H. Vail & Co., New York. Cloth, price $7.00.

It is a satisfaction to welcome a work which is the result of intelligent, disinterested, thorough scientific research. Such is the one before us. It represents the results of more than ten years' devotion to histology, and will undoubtedly mark an epoch in that branch of science. While principally from the pen of Dr. Heitzmann, it contains a number of articles by others who have worked with him, or in the same direction; among these we may name Drs. Louis Elsberg, H. G. Beyer, U.S.N., Jeannette B. Green, John A. Rockwell, etc. These various associate authors have developed some special lines of observations which have a place in the general scheme of Dr. Heitzmann's book.

The fundamental difference between the histological theory of this work and those of other writers is the assertion that the doctrine of isolated cells as the basic form of organic life, as taught by Virchow, is erroneous. The real basic form is the protoplasm or bioplasson, and cells assume activity in the phenomenon of life, as they are brought into contact, as they unite and anastomose, and thus form an inter-connected network. The living contractile matter is not the cell, but the nucleus, nucleolus or contained granules.

The practical results of this new view are striking in the extreme, and offer the promise of wide gains in the fields of pathology and diagnosis. It is perfectly possible for the practiced microscopist to judge accurately of the general condition of the system, and even detect the presence of certain diseases by the appearance of the blood corpuscles alone. "In fact," says the author, "the microscope reveals so much of the general health of a person, that more can be told by it, in many instances, than by the naked eye, or by physical examination" (p. 61). Where the enthusiastic advocates of this method of research would draw its limits, we know not. One young physician is mentioned who refused to marry the girl to whom he was engaged, until she had consented to have some blood drawn and submitted to Dr. Heitzmann for his opinion as to whether the granules were just what they should be. We hardly know whether to say that we are glad or sorry to add that, after due scrutiny, he recommended the marriage!

The ground covered in the book may be briefly stated as follows: The author first reviews the phenomena of living, healthy protoplasm, tissues in general, connective tissue, nerve tissue, muscle tissue, and epithelial tissue. Thence he proceeds to discuss pathological processes; as inflammation, tuberculosis and tumors. Passing from these he takes up in order the skin, the digestive tract, the teeth, the liver, the respiratory and urinary tracts, the urine, and the genital tracts of both sexes.

The text is illustrated with 380 original engravings, made after very accurate preparations by Dr. Heitzmann. The literary finish of the book is open to criticism here and there, but not in important points. But a very important point is the total absence of an index. We cannot recommend any one to purchase a scientific work of 800 or 900 pages when the author and publishers have been so negligent of what they owe the reader, as not to supply this indispensable requisite to the proper use of the book.

The Library Index. R. G. Hutchinson, 44 Maiden Lane, N. Y. Half-bound. Price $2.50.

Physicians are, at any rate ought to be, a book-buying, library-owning class of people. Even a small library is more available if it has a well-arranged catalogue. Mr. Hutchinson has prepared a neat, well-made blank book, sufficient for a library of about 1800 titles. The pages are ruled with printed headings, giving title, author, publisher and date of publication, number of volume, size, style of binding and remarks. He will mail the book on receipt of price.

Speech and its Defects, Considered Physiologically, Pathologically, Historically, and Remedially. By Samuel O. L. Potter, M.D. Philadelphia: P. Blakiston, Son & Co. 12mo, pp. 114. Price, cloth, $1.00.

This is an essay which, as a thesis, took the Lea prize at the Jefferson Medical College. The author states that he himself was a sufferer from "dyslalia," and has been led to give the subject unusual attention. It is, in fact, a treatise on stammering and stuttering, and the general title of the book is wider than its subject matter. The views of the author are very judicious, and he exposes with an unsparing hand the tricks of the charlatans, the self-dubbed "Professors," that go about the country pretending to cure the unfortunates who fall in their way. He also sets forth clearly what the real means of relief are. An excellent bibliography of the subject closes the volume.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

FALLACIES IN MEDICAL TEACHING.

It is taken as prima-facie evidence, that if a man is a professor in a large college, a hospital physician to a populous hospital, and enjoying the well-earned reputation of a learned member of the profession in a great city, he is qualified better than any one else to teach medicine.

On the other hand, it can be shown that all these seeming advantages present also serious drawbacks to the success of the teachings of such a man. Not to his personal success as a teacher; we do not mean that; but to the value of his teachings. We maintain, and shall show, that just these apparently favorable surroundings incapacitate him from doing the most good to students.

To illustrate our position at once, from a country where it can be most readily demonstrated, we turn to Germany. As a rule, a professor in a German university has been a most earnest closet student; he has spent his nights and days in the library, over the dissecting table, in the hospital wards, at the dead room, peering through the microscope, writing for the press: has he ever seen the normal rise, development and termination of a disease? Quite likely he has not. When a patient is brought to a hospital, the disease has usually progressed far; the patients there are under entirely different surroundings from those in private life; the circumstances that it is, and must be, in a large city, bring into action a whole series of influences with which the average practitioner has nothing to do.

When the professor has acquired fame, is he more favorably situated to see disease as the ordinary physician meets it? No, even less so. He is called in as consultant in desperate cases, for infrequent visits, and has no time to watch a case. His opinions, his mode of practice, his acquaintance with the forms of disease, his estimate of the actions of medicines, must all be necessarily made up from a materially different series of observations to that of the great mass of his professional brethren. Strictly speaking, he is not qualified to give them the best instruction which they are capable of receiving; his doctrines must be misleading and his observations delusive.

We believe this is conspicuously shown in Germany, and the results of this state of affairs are very marked there. It may be freely conceded that in many branches of theoretical medicine the Germans stand easily ahead of the world; and it must be added, with equal justice, that in practical medicine, in the therapeutics of diseases they are far, very far, behind either the English or Americans. Any one who will examine the mortality statistics of the German hospitals will be shocked at the heavy death rate; but if he follows the professor through the wards, or reads many of the issues from the press, and then learns the indifference and often contempt with which the therapeutics of a case is dismissed, he will see the cause of this fatality. It has actually progressed so far now that a student or young physician who busies himself earnestly with the problem of curing disease, of the definite removal of sickness and restoration to health, is looked upon as of limited intellect,

and with little grasp on the greatest questions of his profession.

This is so already in Germany, and it is becoming so in this country. Our eminent teachers are too busy with lecturing, reading up, hospital work, writing, and consulting practice, to have any time for the patient observation of disease as it is seen by the physician of limited family practice, or the country doctor. We urge that this be recognized all around, and that the profession be on its guard against that decay of practical medicine which has struck the Germans and undermined their usefulness like a dry rot.

DANGEROUS OCCUPATIONS.

The recent death, in New York, of one of the line-men of the Brush Electric Light Company suggests some thoughts on the precautions that ought to be observed in the employment of men for all labor that may be attended with danger to life.

It seems that this man was employed to break and connect again the electric wires, while the current was passing through them. To do so, it was necessary to scrape off the insulating material, in order that the bare wires might be joined.

The company had issued a notice to all men so employed that they must uncover but one wire at a time, and after reconnecting the severed ends, to wrap the exposed parts with insulating material before exposing the second or continuing wire. This man had been in the employ of the company for more than a year, was considered one of their most intelligent men, and was, therefore, presumably aware of the fatal danger that might arise from disregard of this precaution.

When he had been at work for a few minutes only, he was noticed to be clutching both the negative and positive wires of the line, and was hanging limp and apparently lifeless against the wires stretched on the pole. His right leg was thrown over the cross-bar, and he swung in mid-air, the wires preventing him from falling to the sidewalk.

When taken down and removed to the Station House, the only marks of violence or disfigurement on the body were on the palms of his hands, which were terribly burned and blistered.

From this it would seem that the cause of death in this case must have been an electric shock received from the man grasping the two wires and thus making a connection between them. If both or one had been thoroughly insulated such a catastrophe could not have occurred.

Therefore we must consider that both wires must have been unprotected; yet it would seem very improbable that a man acquainted with the danger (as this man must have been) of handling two unprotected wires, would do so.

It could, however, happen that, being daily accustomed to work among electric wires (familiarity breeding contempt), this man, to save time, may have scraped the insulating material from both wires consecutively, intending to handle only one at a time; to complete the first step in his work, to cut, re-unite and insulate the first wire, before he touched the second.

After he had performed the first part (or scraping) he may have been rendered unconscious, by an attack of epilepsy, heart-disease, or cerebral inactivity from some other cause, and feeling himself falling, grasped for the nearest support, and seizing the exposed wires, received the fatal shock.

This is only an hypothesis, but it is one worth consideration.

The autopsy may not have revealed any lesion to account for this sudden attack of unconsciousness, but nevertheless it may have occurred, since pathology is far from being a perfected science. If one wire were found perfectly insulated, then, of course, our theory falls to the ground.

But the point we desire to make still holds good.

In many trades men are exposed in such dangerous positions that very clear heads and complete possession of full mental faculties are at all times requisite to prevent the occurrence of fatal accidents.

Thus painters, riggers, roofers, and so on, are so exposed that any slight attack of unconsciousness, even vertigo to a slight degree, may cause them to lose their footing and to be precipitated a fatal distance.

When men apply for service in the army and navy they are subjected to critical physical examinations, to determine their fitness or unfitness for the arduous duties they propose to undertake. This rule applying even to those whose occupation will be of such a nature that some forms of physical infirmity would not materially interfere with their usefulness.

Would it not be wise, in the interests of humanity, to subject all men proposing to engage in work that required constant self consciousness, a temporary absence of which might prove fatal, to a preliminary examination?

This idea is seemingly a utopian one, but is it impracticable?

More difficult tasks have been accomplished.

To make such a proposition a reality rests with the medical profession; they must instruct the public more fully in regard to the dangers hinted at, and suggest, re-suggest, and continually advise, the only available remedy.

THE SCIENCE AND STUDY OF HYGIENE.

That hygiene is truly a science, and a most progressive one, every reading physician will admit.

That it has of late and is to-day making rapid strides towards the position of an *exact* science, must also be conceded.

That it is not properly or sufficiently recognized by the medical profession in our country, is the third of the propositions which we feel sure facts will substantiate.

The universally recognized truths that we have in certain instances the absolutely sure means of preventing the inroads of disease, entitle the branch which teaches such precautions to the dignity of a science; this, without further argument, establishes the first section of our first proposition.

The rapidly increasing space devoted to the bygienic researches of great men, in our leading professional journals, demonstrates the progression of the science.

The wonderful and *accurate* discoveries of Pasteur, Koch, Wood and Formad, and others, all of which have an intimate relation to and bearing on the science of hygiene, tend to entitle it to rank among the exact sciences.

Thus, then, in a few words, we have given our reasons for all of our assertions save the last.

That hygiene is not adequately appreciated by the profession of this country, is abundantly evidenced by the position which it holds in the curriculum of some of our best colleges.

Constituting, as it really does, the most important, because the most beneficent branch of medical science, its teaching is relegated to an auxiliary course, upon which attention is not compulsory, and, therefore, very meagre.

It thus is made to adorn, rather than to form an important portion of, professional education. Ranking with botany, zoölogy and comparative anatomy, it does not assume, in the eyes of the inexperienced student, that magnitude to which its importance entitles it. He who may have the leisure and inclination to become an *accomplished* physician will attend this extra course, and thus acquire some little smattering knowledge of hygiene, while the majority of students will leave their alma mater with no knowledge or appreciation whatsoever of this most sublime science and fascinating study.

There are two classes of physicians, to each of which the science of hygiene will present itself in a very different aspect.

To the man who practices medicine *solely* as a *business*, who constantly considers *only* how much money he can make out of it, hygiene presents itself as an enemy, as a science to be discouraged, since it may tend to reduce his pecuniary gains.

To the noble-minded and philanthropic physician, who can see more than mere "*profit or loss*" in the grand profession of medicine, hygiene will present itself in its true aspect, as the noblest science to which the mind of man can be devoted. Yet to this selfish class, who would

belittle sanitation, because it would, so to speak, rob them, a few words are necessary.

When the public, when your patients, come to recognize hygiene in its true light, and to place it where it properly belongs, you will not lose by this advance.

Your duties will become twofold; for not only will you be called upon to cure disease when it has become established, but you will also be requested, by sensible persons, to instruct them how to avoid disease; so that you will thus have both fools and wise men for clients.

When the public learn that almost all diseases are preventable, and that we nearly all *ought* to die of old age, they will be just as anxious to have their physical condition inspected at stated intervals, and to receive advice that will tend to retain a good condition or to repair a vitiated one, as corporations now are to have boilers regularly inspected and repaired, that subsequent disaster may be averted.

But that the public may recognize the inestimable value of hygiene, the profession must first be made alive to its importance, and to accomplish this, the institutions of medical instruction must take an actively progressive step.

The chair of hygiene should be made a part, and an exceedingly prominent part, of the regular winter curriculum; the science should be thoroughly taught, and a most rigid examination be required in this branch, as one of the essential requisites to graduation.

England is rapidly showing its appreciation of hygiene; do not let us wait in this important matter, as we do for the fashions in dress, an indefinite period, to follow this worthy example. Let some prominent institution start the suggested measure and all the others will fall into line; the fruit is ripe, and he who plucks it first can have the largest bite.

The Parkes Museum of Hygiene.

H. R. H. Prince Leopold, Duke of Albany, has consented to become the President of the Parkes Museum of Hygiene. Many of the most distinguished names in England are found among its list of life members. It will no doubt be of much service in promoting and fostering an interest in sanitary matters.

Notes and Comments

The Quarterly Compendium of Medical Science.

In compliance with the wishes of many subscribers, we shall hereafter issue the Compendium of Medical Science *quarterly*, instead of *half-yearly*, as heretofore. It will appear in the first week of January, April, July and October. The four numbers will make a volume the same size or somewhat larger than the two numbers of the Half-Yearly. The arrangement of matter will be in a general way the same.

It is believed that this change will prove acceptable to all who have hitherto taken the Compendium, and will, we trust, recommend it to many who have not yet subscribed for it. As a quarterly, it will embrace all that is new and valuable in the medical literature of both continents. It will contain a synopsis of everything of the first order of importance for the physician and surgeon to know. The advance of medical science all the world over will be faithfully mirrored in its pages.

We especially urge all subscribers to the Reporter to send us $6.00 for 1883, and take the quarterly Compendium along with the Reporter. We can assure them they will find it repays them tenfold.

Threatened with Typhoid.

A correspondent of the *Boston Medical and Surgical Journal* says: Let me give you a little item of personal history.

Several years ago I was an inmate of an institution in which typhoid fever showed itself. Two young gentlemen with whom I was intimately connected, were successively stricken down with it. (The conductor ventilated the sewers of the neighborhood directly under their windows.) One of these cases remained in the house, and was in part under my care. The diagnosis in each case was confirmed by gentlemen whose official position guaranteed their ability. After the disease was fully established in the second case, I found myself afflicted with a slight headache, marked dullness, quickened pulse, and, if I remember, a raised temperature. Fearing that my condition was the result of imagination (I had naturally dwelt much upon the sickness of my friends and my similar exposure), I applied for advice to two physicians outside of the institution. They both told me I was threatened with typhoid, and advised me to clear out, which I did. In the country I very soon returned to my normal state, and after per-

haps a week or ten days returned to my duty; long before either of the cases mentioned above had even begun to convalesce. There can be no doubt, at least there was none in the minds of my advisers, that if I had stayed I should have been the victim of typhoid; I was threatened with it, and the catastrophe was averted. Such cases are not rare. This one merely serves as an example.

The Respiratory Centre.

In *Pflüger's Arch.*, xxv, Dr. J. C. Graham makes a preliminary communication in regard to a *new specific regulatory nervous system* for the respiratory centre.

In the abdominal cavity are spread sensitive fibres, which have an analogous form to the respective fibres of the vagi, and form, in connection with them, the regulatory nervous system of the pleuro-peritoneal cavity. (1) On central irritation of the splanchnics, laid bare and prepared in the abdominal cavity and severed, always an expiratory stand-still of respiration sets in, the diaphragm completely collapses, while the abdominal muscles as expirators contract violently. The same result can be noted, if both vagi and sympathetic are cut through in the neck. (2) On division of the medulla oblongata in its most anterior part, as well as after division of the spinal medulla, between the 11th and 12th dorsal vertebræ, irritation of the splanchnics causes also, without exception, cessation of respiration during expiration. If the spinal cord is divided between the 4th and 5th dorsal vertebræ, irritation of the splanchnics has totally lost its effect. (3) In dyspnœa and apnœa also, irritation of the central stump of the nervous splanchnics exerts this specific influence on respiration; in apnœa after irritation the apparently collapsed diaphragm assumes a still plainer expiratory position.

These experiments tend to explain, to a great extent, disturbances of respiration which are so frequently noted in dyspepsia, as well as in other morbid conditions of the alimentary canal. It never seemed to us clear why, for instance, in ascites of high degree, the patient should so frequently have a similar trouble in expiration—not being able to get the air out of the lungs—as is noted and well-known in cases of asthma due to emphysema of the lung. That, in dropsy of the abdomen, inspiration should be difficult, was easily explained, in consequence of the encroached space, but the observations of Graham show also how disturbances of expiration in such cases, may be brought about.

Pathology of Herpes Zoster.

In two cases of herpes zoster, Dr. E Lesser found a morbid condition of the respective spinal ganglia; in the one existed an inflammatory process, evidently started in consequence of a tubercular pleuritis. In addition to these two cases, which we find described in *Virchow's Arch.*, lxxxvi, p. 390 *et seq.*, L. cites also two other cases, observed during life, in which the herpes zoster made its appearance in cases of kyphoskoliosis of the thoracic spine. The eruption, following the course of a spinal nerve, showed itself here on the side of the convexity.

Morbilli Scarlatina.

An eight-year old boy was affected with mild catarrhal symptoms of the respiratory passages and of the conjunctiva, being attacked by measles. On the fourth day, when the temperature had resumed its normal again, it suddenly ascended; there was enlargement of the spleen, angina and scarlatina exanthem, with miliary eruption. On the sixth day, mealy desquamation of the face, neck and throat; but synchronously the scarlatina eruption spread further; stomatitis developed itself, and then desquamation in flakes took place, which outlasted the mealy desquamation. Convalescence set in and the boy got well.

While it is generally thought that two such infectious diseases will not break out in the body at one and the same time, in this case their consequences, at least, seemed to have gone hand in hand with each other.

A Case of Fistula of the Pancreas.

The following rare and exceedingly interesting case is reported by Dr. D. Kulenkampff, in the *Berlin. Klin. Wochenschrift*, 1882, No. 7, and referred to by Prof. L. Rosenthal, in his *Centralbl. f. d. Med. Wissensch*, 28, 1882, p. 511.

A laborer, æt. 39, received a severe injury, being hit on the abdomen. After the grave inflammatory symptoms had apparently all subsided, the patient felt comparatively well, but complained of gastric disturbances. Gradually a tumor developed itself in the epigastric region, and growing to the size of about a child's head. As he was uncertain in regard to the diagnosis, Dr. K. cut carefully, first through the abdominal wall, in the linea alba; then he punctured the swelling with Potain's apparatus, and about a wine-bottleful of a clear fluid was discharged, containing a large quantity of albumen, but no

"Bernstein" acid. Later the peritoneum was attached to the abdominal walls, the tumor opened, and a litre of the same fluid taken out. He then established drainage, and daily ¼ to ¾ litre of this fluid was discharged. The wound closed, but a small fistula remained, and notwithstanding all endeavors, the skin surrounding it continued sore. This fact caused the suspicion that he had to do here with a pancreatic fistula, and the chemical analysis, which was made by the chemist, Dr. Hausmann, confirmed this. The fistula soon afterwards closed forever. We may gain from this case some approximate idea of the amount of pancreatic juice secreted within 24 hours in the human being.

Tonsillotomy and Hemorrhage.

Dr. N. A. Powell read a paper on this subject before the Ontario Medical Association (*Canada Lancet*). Statistics show that dangerous hemorrhage occurs in about 1 per cent. of all tonsillotomies. After the operation, the surgeon should not lose sight of the patient for some hours, but should make frequent and careful inspection of the throat. Blood may pass into the stomach, and give no external sign till blanching of the face or faintness shows its loss. If he finds hemorrhage in unsafe amount, he should resort at once to direct pressure, either with the fingers or a sponge, on a firm holder. After this, he should examine for bleeding points, and twist them. Cold should be applied, and in the failure of all measures, ligature of the external carotid, or of the common trunk, may be considered.

Resorcin in Cholera Infantum.

Dr. M. Cohn, in his inaugural thesis at Stuttgart (*Centralbl. f. d. Med. Wissen.*, 1882, *p.* 512), speaks of the effect of resorcin in cases of cholera infantum. He made use of a solution of 0.3 (5 grains) resorcin, six drachms of water and about two drachms of simple syrup. He observed no disagreeable side effects, and of 35 children who had suffered from summer complaint, 30 rapidly regained their health. These observations were made at the University clinic for diseases of children, in Stuttgart. In no case was noted any bad results, and Cohn considers this remedy almost a specific in catarrhal inflammatory conditions of the mucous membrane of the alimentary canal in children. He found it also uniformly successful in all cases of stomatitis, aphthæ, etc.

Specific for Sore Throat.

After a large number of observations, Dr. Robt. N. Hormazdji, of Cheltenham, has come to the conclusion, that in all acute cases of *tonsillitis* salicylate of sodium is a specific, while in chronic cases it seems to possess no effect whatever. He recommends about 15 grains of the remedy every hour, till the most urgent symptoms are relieved, when only half the dose is administered. At the same time he employs a gargle, consisting of about 10 grains of the salicylate of sodium, one ounce of glycerine and three ounces of water. He found the remedy especially specific in its effect in very acute and severe cases, as also in the angina of scarlatina, and of erysipelas.

Function of Spleen and Bone Marrow.

Dr. Theo. Korn (*Virchow's* 5 *Arch.*, lxxxvi, p. 406), examined the hæmatogenesis in pigeons, withdrawing from a series of animals, in intervals of five days, from five to seven grms. of blood; he then repeated the same experiment in animals the spleen of whom had been removed four weeks before. The normal power of resistance of pigeons against venesection was not diminished by the extirpation of the spleen. In the first series, Korn demonstrated, in every case, atrophy of the spleen. In both series the observation was made that the marrow of the bone became richer in blood, while a great part of its fat seemed to be absorbed and made use of for other purposes. While these experiments clearly show that the spleen, at least in birds, is of no importance for the regeneration of the blood, they demonstrate the fact that the marrow of the bones undoubtedly participates in the formation of this fluid, which is the more apparent in birds, as many of their bones do not contain any marrow at all.

Bone Gummata.

From careful investigations made by Dr. Chiari, in Vienna, we learn, that in syphilis, *gummata* in the *marrow* of the bones happen far more frequently than has generally been believed to be the case. They rarely appear on the surface, and are, therefore, seldom recognized. We are well aware that the osteocopic pains, when they are not due to periosteal affections, have not found any explanation as yet. From the results of the post-mortem examinations by Chiari, we draw the conclusion, that in all such cases we have to do with such gummata in the

marrow of the bones. The remarkable influence of iodide of potassium on all gummatous formations would also explain its rapid beneficial action in such obscure osteocopic pains.

The Influence of Blood Pressure on Cardiac Inhibition.

The *Lancet* says that Messrs. Sewell and Donaldson have been investigating the effect of alterations of blood pressure within the cavities of the heart upon the inhibitory function of the pneumogastric nerve. With increase of the venous pressure, while the arterial pressure remained constant, it was found that the inhibitory effect of an electric stimulus was lessened. Variations of arterial pressure did not have any effect upon the action of the vagus.

Displacement of the Bones of the Skull.

In the *Revue de Méd.*, 1882, ii, p. 112, Dr. I. Parrot reports three cases of tubercular meningitis in children, nine months, two and three years old. The cases ran a very rapid course. The interesting observation Parrot made on these cases was a displacement of the bones of the roof of the skull. The bones separated up to 3 mm. from each other. The space between them was filled by a sanguinolent fluid. We must remember that they were not cases of acute hydrocephalus, where, in consequence of extravasation, such separation of the bones, not firmly united as yet, would have been most natural, but cases of tubercular meningitis, where the simple inflammatory exudation produced this result.

An Abnormally Long Processus Styloideus.

Two cases, in rapid succession, appeared at the University clinic for internal diseases, in Vienna. Both persons complained of great and continuous difficulty in swallowing, and in both an unusual prolongation of the styloid process was detected as cause of the disturbance. The process could be felt behind the tonsils. In the one case the right process was elongated, in the second, both. In the latter both tonsils were of the size of a large bean, without presenting any sign of inflammation, and pushed forward. In the first case it was possible to fracture the bone, and then to give the broken piece such a direction that the impediment to swallowing ceased and never reappeared, while in the other case they were not able to fracture the bones.—*Wiener Med. Wochenschr.*, 1882, *No.* 5.

Ether Inhalations in Angina Faucium.

In the *Riv. Clin. di Bologna*, Prof. Concato recommends ether spray as an inhalation in sore throat. The patient takes the exit tube of a Richardson's spray producer in his mouth, and sulphuric ether is sprayed against the pharynx for three minutes; this is repeated every three hours. Six cases were cured without other remedies. Each case began with a rigor and a sharp attack of fever, temperature 104° F. There was swelling of the sub-maxillary gland, and pain and difficulty in swallowing. The tonsils were swollen and protruding.

Hermaphroditism.

The *Lancet* says that a woman was recently delivered, in the British Lying-in Hospital, of a living child, which presented the characteristics of so called spurious hermaphroditism. There is a large penis or clitoris, with a prepuce bound down by a strong frænum. Immediately below this is a small canal, capable of admitting a good-sized probe, and from which urine is voided. The penis (?) is of natural size for a newly-born infant, and presents at the apex a well-marked depression, resembling the external urinary meatus. The scrotum (?) is divided, and resembles the female labia, but no trace of testes can anywhere be discovered. So equivocal are the appearances that it is at present impossible to determine the sex of the child. Dr. Fancourt Barnes, whose patient the mother is, seems to incline to the opinion that the type is rather feminine than masculine. If the child lives, it will, in all probability be shown to the members of the Obstetrical Society, when the problem of the sex may be solved.

The Last Thing in Incubation.

The *Lancet* is authority for the statement that M. Tarnier, of the Maternity Hospital, in Paris, has had constructed a box which is very similar to the incubators used for poultry. Into this he places all the weakly and sickly children.

This box is divided into two compartments, the lower one being used as a reservoir for hot water, while the infant is placed in the upper one, which is well stuffed at the sides and fitted with a sliding glass cover. The temperature is maintained at 86 degrees, Fahrenheit, and M. Tarnier has found that by keeping infants in the incubator for a period varying from two days to six

weeks their vitality is enormously improved. He has made experiments upon five six-months, children, six seven-months, and thirteen eight-months, children, and he has only lost two of them, whereas, according to his statement, three-fourths of them would have died but for this adventitious aid to vitality.

Traumatic Ophthalmoplegia.

Dr. Gruening recently presented to the New York Society of German Physicians (*New York Medical Journal*) a man who, after receiving a sharp blow on the left eye became blind. The lids were discolored, upper lid paralyzed, and bulb immovable, so that there was paralysis of the motor oculi, abducens, trochlearis and optic nerves. The pupil was stationary and large. The diagnosis was, fracture of the base of the orbital pyramid, with rupture of the optic nerve and compression of all the nerves passing through the superior orbital fissure. Iodide of potassium, with hypodermic injections of strychnia and faradization constituted the treatment. At the present time the bulb could be moved slightly in all directions. Fracture of the orbital pyramid is usually followed by atrophy of the optic disc.

Hydrophobia Cured with Aconite.

Dr. D. H. Cullimore reports, in the *Lancet*, the case of a boy aged ten years, who, some three weeks after being bitten by a supposed rabid dog, commenced to exhibit symptoms of hydrophobia. As soon as the nature of the disease was suspected, strict quiet was enjoined, and he was given one minim tinct. aconite, six grains bromide potassium, six minims tinct. cinchona, to half an ounce of water, to be taken every half hour for twelve doses and then three times a day. He was restricted to milk and arrow root. In about two months he was discharged, cured. The author gives a long theoretical explanation of the action of aconite in this disease, which it is unnecessary to notice here.

Oxygenated Water.

M. Brochin reported some experiments made by M. Paul Bert and Becquard at a recent meeting of the Société de Médecine Pratique (*British Medical Journal*). Oxygenated water was used with great success in the treatment of purulent cystitis, ozæna and ringworm; also, internally in uræmia and diabetes. To preserve it, it must contain an acid, for which hydrofluoric acid is used. A certain amount of oxygen is liberated from this water, in the form of ozone, and it is in this way that it acts.

Bilateral Herpes Zoster.

Dr. Zinsser reports a case of this affection in the New York *Medical Journal*. Bilateral herpes zoster is very rare. But three cases are reported. The attacks were quite frequent, and were regularly preceded by a peculiar train of symptoms similar to sea-sickness. The patient is otherwise in good health, strong, and by no means hysterical. His disease is probably of central origin.

Correspondence.

Congenital Occlusion of the Rectum.

Ed. Med. and Surg. Reporter:—

August 17th, 1882, Mrs. S., of this place, aged 28, was delivered of an apparently healthy female child, by my partner, Dr. J. A. Rawes. The child urinated freely that day, but had no motion of the bowels up to the 19th, when we were called in. It refused to nurse, lay quietly, but would occasionally strain violently. An examination revealed a natural anus, but on attempting to introduce the end of a female silver catheter, we met with an obstruction, half an inch from the external parts. On introducing a speculum it revealed a complete cul-de-sac, the bottom presenting a dense fibrinous structure. Assisted by Dr. J. H. Mack, an experienced practitioner, we etherized the child, passed a catheter up the vaginal canal, and introduced a bistoury, guided by the catheter, through the bottom of the sac, in the direction we hoped to find a termination of the rectum, but failing to reach it, resorted to a trocar, passing it up to the promontory of the sacrum, when we desisted and abandoned the operation. The parents objected to our making an artificial anus, and we were compelled to leave the child to its fate. It died on the 20th, and on the 21st we made the autopsy. The intestines were very much distended with gas, but they and all the abdominal viscera were in their normal situation, excepting that the descending colon terminated in an expanded pouch, on the left lateral wall of the belly, above the pelvic basin. On inflating it with air (after removing the meconium that distended it), we could discover no opening of any kind, but attached to the end and extending down the entire space usually occupied by the rectum, was the same dense fibro-cellular structure that formed the floor of the anal cul-de-sac. The health of the mother had been good during her gestation, and she had received no shock or fright that could be assigned as a cause for so deplorable a malformation.

H. E. W. Barnes, M.D.

Macksburg, Iowa.

State Medical Society of Virginia.

ED. MED. AND SURG. REPORTER :—

The State Medical Society of Virginia, which lately held its twelfth annual session at the Fanquier White Sulphur Springs, had a good attendance ; the average number is about fifty Fellows, among whom may be mentioned, Professors Hunter McGuire, and James, of Richmond, L. B. Edwards, editor of the *Virginia Medical Monthly*, Drs. Dabney, of Charlottesville ; Jackson, of Norfolk ; Fauntleroy, of Staunton ; Bedford Brown, of Alexandria ; and Prof. I. L. Cabell, of the University of Virginia, President of the National Board of Health.

Hon. James M. Brooks, an eminent lawyer of Warrenton, delivered the address of welcome. It is to be regretted that so few papers on medical and surgical topics were prepared for the occasion. Dr. Bedford Brown's, on "Infantile Pneumonia"; Dr. Taylor's, on "Abdominal Surgery," for which he received a fifty dollar prize, and Dr. Elzey's, on "Alcohol," for which was also awarded a prize for the same amount, were all excellent productions. Dr. White, of Richmond, and Dr. McKenzie, of Baltimore, both youthful, described diseases of the eye and ear with marked ability.

The resolution condemnatory of the action of the New York Medical Society admitting irregular and homœopathic physicians to membership, contrary to the spirit and letter of the Code of Medical Ethics, which governs the profession in the United States, was unanimously adopted.

The society adjourned to assemble next year, as the guests of the proprietor of the Rockbridge Alum Springs. Whether such precedents for the sober-minded M.D.'s (usually so at home) to convene at fashionable watering places, will prove advantageous, is questionable.

NOUS VERRONS.

NEWS AND MISCELLANY.

Pharmacy and Malaria.

The Boston *Journal of Chemistry* says that at a recent banquet of the Illinois Pharmaceutical Association, Mr. E. S. Baldwin, an editor, responding to the toast of "The Press," and referring to old times, said : "It did not then take a student two years at a pharmaceutical college to learn that when he could not read what the doctor had written he should put in aqua pura, syrup simplex, and podophyllin. No, sir ; this blessed system was not invented then. When we remember what our ancestors suffered on our behalf, we no longer wonder that they had rugged constitutions, or that we have been permitted to enjoy the effect of their tonics in the shape of hereditary dyspepsia. . . . On entering a modern drug store, you walk boldly up to the be-moustached and be-jeweled clerk. If you know your business, and it is a temperance town, you wink at the fellow, and say something about malaria. It is a matter of indifference just what you say. The single word 'malaria' is the golden open sesame. . . . Whenever I see a man coming out of a drug store, and wiping his mouth on the back of his hand, I realize to its full and awful extent the hold that malaria has on this unfortunate people. What the drug stores in towns where a strict license law prevails would do without 'malaria,' is a hard problem."

Science on the Stage.

From the Boston *Journal of Chemistry* we learn that it is proposed to try a novel experiment at Paris, by producing a series of scientific dramas at one of the theatres, with the object of combining amusement with instruction. Three plays have already been provided, and their titles clearly indicate the direction in which the audience is to be instructed. The titles are : "Denis Pepin, or the Invention of Steam ;" "Kepler, or Astronomy and the Astrologer," and "Gutenberg, or the Invention of Printing." The result of this new dramatic venture will be awaited with interest. Its success may be the inauguration of a new era in science teaching. A most excellent idea, which we hope will be carried out.

Egyptian Treatment of Syphilis.

In the course of an article on "Medical Notes of Travel in Egypt," by Dr. Josiah Williams, in the *British Medical Journal*, occurs the following :—

The native treatment of syphilis in young girls is very primitive and very barbarous. Close to the town (Souakin) in the Red Sea, is a little island, called originally Sana Gin, and from which the town takes its name. The girl is taken across to this island by six women ; she is then laid naked on her back ; on each arm and each leg sits a woman, another on her chest. The operator, another woman, who is provided with a sharp sea-shell, scrapes away in the vagina until she is satisfied that all diseased parts are removed, and then, utterly regardless of the shrieks of the girl, gets a handful of sand from the sea, and rubs that in. The disease is then supposed to be cured, by this rather rough operation.

Sydenham.

Of Sydenham, Dr. Oliver Wendell Holmes says : "He had his hypotheses, like others of his time ; he talked about the humors, as preceding generations had done ; but he kept his eyes open, he watched the progress of disease, he noted the influence of times and seasons, he recognized the meaning of the efforts of nature in the cure of disease. He ordered free ventilation for diseases in which the patient had been "stifled in bed ;" he directed horseback riding for consumptives ; he prescribed a roast chicken and a pint of canary for a nervous young man whom the pedants and the pathologists of his day would have probably bled and drenched ; in short, he was a man of excellent judgment and much more than common sagacity, and did not allow his theoretical speculations to blind him to the facts of disease before his eyes. It is almost two hundred years since Sydenham died,

but there is wisdom in his writings which never grows old."

A Drunkard's List.

It is announced, in the *Journal d'Alsace*, that, in pursuance of a recent decree, the authorities of the Haute Alsace have issued a list of the drunkards in the town of Sainte Marie aux Mines and the neighborhood. The number of these persons is thirty-one; the youngest being twenty three years of age, and the oldest sixty-eight Innkeepers and others are, in future, forbidden to sell intoxicating drinks to any of those who are thus advertised.

An Enterprising Undertaker.

The *British Medical Journal* says that an enterprising London undertaker has issued a circular to medical men, asking for introductions to funerals, and offering commissions. The *Journal* very properly remarks that this is an insult to those to whom it is addressed, and will certainly tend rather to injure than benefit the party in question.

Pathological Society.

At a stated meeting, held Thursday, October 12th, 1882, the following officers were elected: *President*, James Tyson. *Vice Presidents*, J. Solis Cohen, E. O. Shakespeare, F. P. Henry, J. B. Roberts. *Secretary*, P. Skillen. *Recorder*, C. B. Nancrede. *Treasurer*, M. S. Meech. *Curator*, Carl Seiler.

The Age of German Medical Colleges.

From the Chicago *Med. Jour. and Ex.*, we learn that the University of Prague was founded in 1348; Vienna 1365; Heidelberg 1386; Leipzig 1409; Frieburg 1454; Griefswald 1456; Basle 1460; Munich 1472; Jenna 1568; Wurzburg 1582; Gottingen 1737; Berlin 1810; Zurich 1833.

Items.

—In England, during 1879, 308 deaths out of a total of 271,496 were ascribed to eczema.

—Dr. Luigi Concato, the celebrated Professor of Clinical Medicine at the University, Turin, is reported to have recently died.

—The death is announced of the celebrated chemist, Professor Wöhler, of Göttingen, at the age of eighty-two.

—The circulation of the *British Medical Journal*, at the last Association meeting, was reported as 11,000 copies weekly.

—Blackmore says: "The common lay mind hates the lawyer, as the lay body objects to the doctor, and the soul is timorous of the parson."

—An anti-vaccination society has been formed at Hartford, Conn. About a dozen persons constitute the organizing membership.

—A combination of ergot, belladonna and iodide of iron is strongly recommended in juvenile nocturnal urinary incontinence.

—Cannabis Americana, locally applied, is the latest treatment for "reasoning mania." The fibre is the part preferred.

—It has been decided in Paris that there can be no binding agreement between a patient and his doctor, the former not being regarded as a free agent.

—There are now only nine states without Boards of Health, and Pennsylvania and Ohio are the only large ones among them. For shame!

—Mrs. Nathanial Montefiore has given £2600 to University College Hospital, for the endowment of two beds, in memory of her late brother, Sir Francis Henry Goldsmid, Bart., and her late son, Mr. Leonard Montefiore.

—Dynamogen is the name of a new explosive, invented by M. Petri, a Vienna engineer. If the enthusiastic claims of the inventor are not an exaggeration of its merits, it will certainly prove a dangerous rival of gunpowder.

OBITUARY NOTICES.

Dr. George A. Ward died at Cerro de Pasco recently. He served as surgeon during the American war, and was, for many years, a professor at Yale College.

QUERIES AND REPLIES.

Mr. Editor:—Believing that the REPORTER is read by a greater number of physicians than any other medical journal in the United States, I ask for information from that great body as to the results, in their experience, of the *hypodermic injection of Morphia* or other medicines *in veins*. Have any of your readers ever observed fatal or very serious effects from this accident? W. S. F., *Md.*

MARRIAGES.

AULDE—McILHENNY.—On Thursday evening, September 28th, 1882, at the residence of Benjamin Jacobs, Bridesburg, by Friend's ceremony, John Aulde, Jr., M.D., and Emmie McIlhenny, all of this city.

BOBERTS—WALLACE.—At the residence of the bride's parents, in the North Highlands, Sept. 20th, by the Rev. R. M. Roberts, the groom's father, assisted by the Rev. Robert Kay, L. G. Roberts, M.D., of Bedford, N. Y., and Miss May A. Wallace, of the North Highlands.

BRUNNER—BAUS.—Tuesday, October 10th, 1882, at the residence of Mr. Joseph Rosenbaum, 2139 Green street, by Rev. L. Y. Graham, Edgar P. Brunner, M.D., and Miss Amelia D. Baus, all of Philadelphia.

DARLINGTON—GARRETT.—On Thursday, September 28th, in the presence of the Mayor, at the residence of the bride's parents, Horace H. Darlington, M D., of Concordville, Pa., and Kate C. Garrett, of Wilmington, Del.

POWELL—SHUMAN.—October 11th, 1882, at the residence of the bride's parents, by Rev. Richard Searing, Wm. R. Powell, M.D., of New York, and Miss Mary Shuman, of Columbia, Pa.

SAURMAN—SHELLEY.—On October 3d, by Rev. Mr. DeMoyer, assisted by Rev. Mr. Stewart, Dr. B. F. Saurman, of Boston, Mass., formerly of Norristown, and Miss Leonora M. Shelley, of Ashland, Pa.

DEATHS.

COXE.—At Baltimore, Md., on Friday, Oct. 13th, Ernest Cleveland Coxe, M.D., aged 32 years.

HOWELL.—In this city, on the 10th instant, Benjamin P. Howell, M.D., in the seventy-fourth year of his age.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

LIGATION OF PEDICLE AROUND DRAINAGE TUBE IN EXTIRPATION OF THE WOMB.

BY J. M. F. GASTON, M.D.,
Campinas, S. Paulo, Brazil.

Abdominal surgery has made such advances in these latter years, that operators are prepared to undertake risks which would not have been warranted in former times.

Excison of the kidney and bladder have been practiced with impunity; portions of the intestinal canal have been removed and the track continued by uniting the remaining free extremities. The extirpation of the ovaries, with the fallopian tubes, is becoming common; and ablation of the womb, whether in the gravid state or diseased, is recognized and practiced generally. So that it becomes the medical profession to investigate the conditions for safe procedure with this class of surgical cases.

The aim of every operator should be to avoid all the accidents which prudent forecast can prevent, in every surgical case; and the present inquiry is more especially directed to averting the bad consequences which are developed in hysterotomy, whether this be limited to a part, or extended to the entire organ. There has existed heretofore a difference of opinion and a divergence of practice as to the propriety and expediency of drainage in laparotomy; and the results of the various modes of proceeding have not tended to relieve the matter of the doubts which gynecologists have in regard to drainage in uterine surgery.

Under the widespread influence of Listerism during several years past, it is not a matter of surprise that the preconceived views of medical men should be unfavorable to the use of drainage tubes, which, at the same time that egress to noxious matters is afforded, give an opportunity for the entrance to a great or less extent of atmospheric air, with those impurities which have been considered a fruitful source of bacteria. But a new era is dawning upon prophylactic philosophy, and the hotbed of germs does not inspire so much dread now as the heavily charged vapors of carbolic acid diffused in a room with the delusive idea of rendering nugatory and inoperative the products of these miasms. This vain search for the invisible cause of trouble, which has brought greater trouble in its train, is fitly illustrated by a notable result in the experience of one of our most distinguished gynecologists, in one of our largest centres of surgical enterprise in America. With a view to have an operating ward put in the best possible condition for receiving cases of females for abdominal operations, the dingy walls were brightened and purified by a fresh coat of paint. What happened to the patients does not appear, but it has transpired that the operator received such an impression from the white lead and essence of turpentine, that he was disabled for weeks, from his detention during several hours in the said ward while giving his attention to an important surgical case, doubtless aggravated by the inhalations of carbolic vapor.

If the germ theory be well founded, all sort of contact with the atmosphere should be carefully avoided in any surgical operation what-

ever ; but the results of experience on the part of some of the most distinguished gynecologists lead to the conclusion that atmospheric air is not such a bad thing as to require that it should be mixed with carbolic spray ; and it is found that occasional contact of a wound or ulcerated surface with the atmosphere is not productive of serious consequences, notwithstanding what may be intermingled with its normal proportions of nitrogen and oxygen.

Should it appear, upon more ample investigation of the causes of blood poisoning after surgical operations, that the offending element develops within rather than from without, it may devolve upon the operator to look rather to eliminating promptly this *materies morbi* than to shutting the door to its escape by closing every outlet for a discharge from a wound. If the ordinary observation as to the mode of restoration in external parts holds good for the incised or lacerated wound of internal parts, it must be clear that in cases suited to the plan of occlusion, the union by first intention, or by plastic adhesion, must ensue, and failing to effect this most salutary process, the closure of any outlet becomes an obstacle to the cure by suppuration. The radical point for decision in the wounds of deep-seated tissues, is, whether they are likely to be aggravated by leaving a channel of escape for the hurtful elements, in all such operations.

It is evident, from the microscopic observations of Klebs, made in 1870, upon the results of gunshot wounds, that micro-organisms play an important part in the degeneration of the vital tissues ; and the demonstrations of Cheyne go to prove that, while many acute abscesses may, no doubt, be caused by micrococci, yet, in some cases, they must be regarded as accidentally present as the result of some state of lowered vitality of the general system. Even Lister allows that many inflammations, more especially chronic inflammations, are caused by the nervous system, and cannot, in any way, be attributed to the presence of micro-organisms.

Thus it appears clear that we are not to seek *ab extra* for the explanation of the various degenerations of structure which occur as the consequence of surgical interference, and that the scarecrow of atmospheric germs is not a sufficient reason to seal up, as it were, hermetically, every wound that may result from accident, or in the course of an operation upon deep seated parts.

The real source of septicæmia is most certainly in the absorption of decomposed fluids that cannot find their exit ; and it would, of course, forestall such a poisoning of the blood to allow, under all circumstances, a free evacuation of such disorganized matter by drainage.

Should there be no effete matter present, there could be no indication for a discharge, yet an open channel of escape can do no harm.

If the thief should have entered the house by some undiscovered route it may be well to raise the alarm, and leave a door open for his escape.

Two cases of rupture of the womb reported by Morsbach and Graefe, in which drainage by the vaginal canal was attended with salutary results, lead to the inference that a drainage tube may be used advantageously through the neck of the womb or through the vagina, under other circumstances than in accidents of this nature.

In the case of Morsbach "it was discovered that there was a rupture of the vagina and cervix uteri, and that the child was in the abdominal cavity, except one foot, which was within the uterus. The foot was seized and the rent carefully enlarged by numerous small incisions with scissors, till it would allow the child to be extracted. The hand was then inserted and the placenta, which was in the peritoneal cavity was removed. Two thick caoutchouc drainage tubes were put into the rent, and a pad of salicylated wool between the thighs. Slight pyrexia followed, lasting a little more than a week, with abdominal tenderness and tympanites. One drainage tube was removed the next day, and the other on the fourth day. The patient got up on the fourteenth day."

In the other case, reported by Graefe, "the uterus was found ruptured transversely, only about three fingers' breadth of its wall remaining entire.

"The peritoneal cavity contained much clotted blood and meconium. It was washed out with a 2½ per cent. carbolic acid solution, and then a thick drainage tube, thirty centimeters long, put into the abdominal cavity and secured by a silk suture to the posterior commissure.

"After the sixth day the parts were irrigated from one to three times daily, through the tube, with a 2½ per cent. solution of carbolic acid. The tube was removed on the thirtieth day."

These cases being of much gravity, and ending satisfactorily, with the thorough drainage by tubes of large calibre, in one of which it was kept up continuously for a month, must go very far towards convincing gynecologists that the cavity of the peritoneum cannot only be washed out from time to time, but can be exposed to contact with the atmosphere without inducing

inflammation or disorganization in its delicate tissues. In both instances the child escaped into the abdominal cavity, and hence there could be no doubt of the laceration of the peritoneal sac, nor could there be any misapprehension in regard to the entrance of the drainage tube within its cavity, so that each case affords a fair illustration of the application of drainage through the neck of the womb in similar operations upon the abdominal cavity. The incision of the external wall of the abdomen does not present such a complication as to set aside the inference from its use in the graver conditions of laceration of the uterine fibres and the investing membrane.

If the abdominal cavity can be washed out with a 2½ per cent. carbolic acid solution, as was done in Graefe's case, and this same cavity left in free communication with the external atmosphere by a thick and long drainage tube, extending outside of the vulva, it goes very far toward setting the matter at rest in regard to the good result of drainage in this class of cases, and at the same time authorizes the reasonable expectation of it in all operations involving the peritoneal and cellular tissues within the cavity of the abdomen. It is well known that the complete exclusion of the atmosphere from any cavity in which blood may be effused favors its absorption without entering into decomposition, and that coagulable lymph may be assimilated under the action of the adjacent parts when shut off from the external communication with the air; yet, withal, serous collections within the peritoneal cavity, as a rule, give trouble, and purulent discharges from any injured surface are liable to be absorbent and induce septicæmia. In view of these unfavorable terminations after operative procedure, it devolves upon the surgeon to provide against such a contingency, and to discover the means of preventing the noxious influence of decomposition within the peritoneal cavity. But it is claimed that this tendency to disorganization does not manifest itself when operations upon the abdominal cavity are accompanied with proper precautions, and that the few cases in which it becomes developed do not authorize the adoption of a measure that is only requisite for these unfavorable results.

This reasoning would be sound if it were practicable to determine in advance the circumstances which lead to such consequences. But the data upon which to form such a judgment are deficient, and when an operation is completed under the observance of every antiseptic rule, there still follows untoward changes that end in decomposition and blood poisoning. These instances are avowedly beyond the reach of correction while the cavity is occluded; and it becomes a question whether to resort to some mode of treatment from the outset, that will obviate such a termination in any case, or to continue a course that must subject a portion, however small, of the cases to this unforeseen evil.

Laparotomy has been divested of many of the dangers which were its constant attendants formerly, and yet fatal consequences ensue, which timely measures might avert, while in others, the resort to evacuation of disorganized fluids, after constitutional disturbance has set in, has afforded such signal relief as to guide us in the future. Should the operator await such developments, or anticipate them by the adoption of a preventive plan of treatment? If it is satisfactorily established by the large proportion of cases in ovariotomy without any drainage, that a change in the mode of procedure would be unwise, this, still, cannot be said of the operations for the removal of the womb and its appendages; and it is here that we may reasonably look for benefit in a judicious application of a drainage tube through the neck that remains, or through the vaginal canal, in complete ablation.

The recent operations for extirpation of the womb with carcinomatous disease of the neck, practiced by laparotomy and through incisions of the vaginal wall, without drainage, and attended with good results, are very creditable to their respective authors, the former being done by Spencer Wells, and the latter by Fenger; yet these are isolated cases, and it is well known how the accumulation of cases changes the inference from statistics. It is worthy of remark, in connection with the success attending these two first excisions for disease of the neck of the womb, that the first only of Olshausen's four cases operated upon through abdominal incisions gave promise of being a success; yet "in this case malignant disease recurred in five months, and death followed sixteen months later;" while this operator cautions us against Bardenheiser's successful results after drainage, it is, he states, "in just such an operation as this that drainage is actually efficient, since in these cases blood and secretions come into contact with but a limited and acceptable part of the peritoneal cavity; and it must be maintained as effectually as possible during the last few days before it is dispensed with, since, when the opened surfaces of peritoneum are about to close, that is just the time when the

peritoneal cavity must be left free from fluids that may cause infection." This testimony of Olshausen in favor of drainage, being the result of a large experience in this operation, is most valuable.

Schröder's experience in this class of cases has been satisfactory, and he uses a heavy drainage tube, resting in the ununited peritoneal and vaginal wound, being retained in position by salicylated cotton wound around it. The results of Freund's extirpation of the womb, with drainage, are also encouraging, and in his view "the danger of the peritoneal aperture is no longer to be considered; indeed, that the keeping open of the peritoneal wound is highly desirable." The advantages of drainage in operations for extra-uterine pregnancy cannot be urged as a legitimate illustration in favor of it for other cases, when the treatment involves the consequences of fresh incisions; yet the untoward results of the occlusion, such as practiced by Goodell in his case, reported to the Obstetrical Society of Philadelphia, June 2d, 1881, should serve to guide operators in the future management of these cases. Tait's report in the "Removal of Uterine Appendages," in the January number of the *American Journal of the Medical Sciences*, presents a result, in case No. 1 of the series, that exemplifies completely the benefits of drainage in abdominal surgery. It is stated that "for about a month after the operation the cavity discharged freely, but then the opening began to close, and the patient suffered much pain. I, therefore, passed a double drainage tube through the cavity, and left it there about six weeks; I then removed it, and the whole track closed in a few days, and this patient remains to this day perfectly well."

A case reported by Thomas, to the Obstetrical Society of New York, April 5th, 1881, illustrates well the benefits of drainage, as the piecemeal steps by which the tumor was removed, and the violence inflicted by the forcible application of the clamps, might have been expected to induce serious consequences, in the unfavorable condition of the patient; yet, with proper drainage, even "the portion of the uterus caught in the clamp sloughed out entirely, and the cavity granulated from the bottom."

On the other hand, a similar case, reported by Dawson, Dec. 6th, 1881, in which drainage was not used, terminated fatally, and "on examination of the wound after death, it was found that the pedicle at the upper portion had adhered to the wound, but the lower angle of the wound was sloughy. Dr. Dawson believed that death was caused by septicæmia, due to the slough following the excessive traction and the pressure from the clamp." But the outside observer who looks impartially at the progress and result of this case, will not fail to perceive that the want of an outlet to the vitiated matter was the cause of the trouble, which might doubtless have been averted by a timely resort to the drainage tube. On the fifth day after the operation "the patient vomited, had diarrhœa, followed by chill, and died a few hours afterwards." If gynecological surgeons would act upon the time-tried precept "that an ounce of prevention is worth a pound of cure," it would save them from mourning over spilled milk, and of repenting, when it is too late to correct the omission of drainage.

The favorable results obtained in many cases, after threatening symptoms have made their appearance, by the adoption of drainage, should encourage the resort to some means of escape for decomposed fluids as a prevention of septic development. Not that a large extent of surface needs to be exposed, for this could not be requisite for the end in view. But some provision for discharge of vitiated matters is certainly indicated in the majority of operations implicating the serous and cellular tissues. If adhesive inflammation in all cases could be certainly counted upon, then, of course, there would be no exudation of fluids to enter into decomposition, and consequently no necessity for any outlet. But the plastic elements of the blood are not invariably disposed to form coagulable lymph, and when degeneration or perversion may ensue, cannot be uniformly anticipated. It thus turns out that we must provide against these cases in advance, and not leave the system to suffer from vicious absorption of fluids that nature seeks to eliminate, and which will find a way of escape if an outlet is left for them. The results of this open treatment of wounds by the German surgeon, Burow, with the use of the argilla acetici as an antiseptic, goes to prove that it is not the influence of the air upon the surface of the tissues involved that is to be counteracted, but the decomposition set up in these tissues which requires correction.

With these practical deductions from the results of experience we may put theory aside and proceed with the execution of such measures as offer advantages in the management of this class of cases, that present peculiar embarrassments to the operator. The difficulties connected with ablation of the womb arise chiefly from the mode of disposing of the pedicle when made through the cervix, and the process of subse-

quent treatment when complete extirpation is required. It will be allowed by all that any plan that may be effectual in securing the incised parts against hemorrhages, and provide for drainage, without any risk of septic developments, ought to commend itself to the consideration of gynecologists. I have, therefore, to suggest the ligation of the pedicle around a metallic tube passed within the canal, if through the cervix, or in the upper part of the vagina, when complete extirpation is requisite. This presupposes laparotomy; and while there are some cases in which the vaginal operation for extirpation of the womb may be expedient, it is generally preferable to proceed with the operation by an opening through the abdominal wall, thus affording a better guarantee for the removal of the organ with all its dependencies. Having made the necessary incision, and ascertaining the parts to be divided in separating the womb, the tube may be passed from the vaginal canal, within the portion that is to remain, and a strong silk ligature may be carried around the tissues, in such a manner as to secure them, outside of the tube, and thus firmly knotted, with the ends remaining each a foot long, to be carried outside of the abdominal opening and held by an assistant. With strong, curved scissors the tissues are to be divided immediately above the upper extremity of the drainage tube, so that the surface of the pedicle shall be on a line with the margin of the tube, thus admitting of a free outlet of any discharge. Should it occur that, in the separation of any collateral parts, vessels are divided which require ligation, the ends should be left, one for each ligature, sufficiently long to pass out through the drainage tube, with the two extremities of the cord that secures the pedicle, and thus carried together through the vagina and out at the vulva, to be tied with a tape around one of the thighs of the patient. If any blood remains in the pelvic cavity, it is to be sponged out with carbolized sponges; and afterwards an oblong carbolized sponge, with a thread passed through it, is to be drawn down into the tube, having the extremity of this thread fastened to the tape with the ligatures. All being thus secured, the external incision in the abdomen is to be closed, while the walls are pressed steadily and fixedly by assistants on each side, so as to expel completely all the air from the cavity. A compress with carbolized oil is to be maintained over the line of sutures in the external incision, and another placed over the vulva so as to preserve the labia in close contact. In this manner it may be expected that union by first intention will be effected promptly in the abdominal incision, and that drainage will be effectually secured.

It is requisite to have the tubes of different calibre, corresponding to cervical and vaginal canals, as the operation may be through the neck of the womb, or excision below the os uteri, through the vaginal canal. The cylinders of either kind should have a circular depression in the external surface, at a distance of half an inch to an inch from the upper extremity, according to the case, in which the ligature is to be fitted when it is tightened around the pedicle. With the intervening tissues which become separated gradually by the pressure of the ligature, there is formed an annular mass, which is retained in the loop resulting from the passage of the extremities through the circle of the ligature, so that, at the end of six days, the tube may be drawn downward until its upper end is on a level with the original line of ligation, and by drawing upon the protruding extremities of the ligature, this band of dead tissues will come away with the ligature, through the tube. The ligatures securing vessels within the pelvis may be left for a longer period, if it be thought necessary, drawing lightly upon each of these daily.

The sponge within the tube, having a thread by which it can be withdrawn, may be renewed daily, and if it should be found impregnated with foul discharges, a $2\frac{1}{2}$ per cent. carbolic acid solution could be thrown up into the cavity and allowed to escape, so as to wash away any decomposed fluids, before replacing the carbolized sponge, or a plug of old linen, which may be more conveniently applied.

The lower margin of the tube should have a perforation through which a strong ligature is looped, and this of sufficient length to pass out of the vaginal canal, so as to be held by the hand of an assistant, when various manipulations are made, thus preventing the tube from moving upward; and this loop should also be fastened to the tape around the thigh in the intervals between dressings, with a view to prevent the escape of the tube into the abdominal cavity when released from the encircling ligation by the shrinking or division of the tissues. It will be observed that, at the outset, three separate classes of cords pass out at the vulva—the main ligatures around the pedicle, those used for tying the vessels within the cavity, and that attached to the lower rim of the drainage tube—all of which are to be fastened to the securing tape around the thigh. The first named

comes away before the others, and the last remains so long as the tube is continued in use for drainage.

After the detached band of tissues from the pedicle has been removed, the tube may be lowered in the canal, whether of the cervix or the vagina, so as to allow the circular raw surfaces to approximate and thus gradually close the opening into the cavity of the pelvis, as it is desirable that complete occlusion be effected when there is no longer any discharge. It will be found advantageous to give the tube intended for the cervix a slight anterior curve at its lower extremity, so as to adapt itself to the relation of the os uteri with the upper part of the vaginal canal when in position.

This curve should correspond very nearly to that usually given to the internal part of a tracheotomy tube, and the other straight arm of the drainage tube, which is to enter the canal of the cervix uteri, corresponds in its relation to the curve to that of the straight portion of a catheter to its curved part in the former, being each proportionally shorter, to adapt it to the surroundings.

In an emergency, a pair of the largest calibre of tracheotomy tubes could serve the purpose of drainage through the neck of the womb, filing away the fastenings from the outer cylinder, and placing the circular shoulder in contact with the os uteri, while the inner cylinder might be plugged with the carbolized sponge, or strip of old linen, being removed as often as requisite for washing out the cavity, and thus facilitating the changes of the material within the tube.

A carbolized sponge, or roll of carbolized cotton, may be impacted against the lower extremity of this extemporized drainage tube, thus maintaining it in its proper position, and this being shut up in the vagina by the action of its sphincter. With a dressing thus made, there would be no communication with the external air, except when the sponges were changed, and the parts being then washed out with a carbolic acid solution, it is presumed that even the most zealous of the advocates of antiseptic measures could not take exception to this proceeding.

In operations upon the eve of delivery, when the os uteri is already dilated, the diameter of the tube may be from a half to three-fourths of an inch; whereas, in those for the ablation of the unimpregnated womb, when the neck is in its normal state of contraction, the diameter of the tube must be less than half an inch, according to the necessities of the case, as observed by previous exploration. The cylinder which is adapted to the excision through the upper part of the vaginal canal does not require to be curved, and should have a diameter exceeding three-fourths of an inch, to be regulated by the circuit of the vaginal wall at the point of selection for the ligature. It is desirable that it should adapt itself smoothly to the exterior surface of the tube, without folds or wrinkles, under the closing of the ligature. As the length of the curved tube suited for the neck depends upon the extent of the pedicle, so as to descend for about an inch and a half below the opening of the os uteri; so the length of the cylinder for the vaginal operation must be modified according to the length of this canal in each individual case, so that its lower extremity shall be retained within the sphincter vaginæ. Thus it is clear that the operator must determine for himself the dimension of the tube or cylinder which may be requisite for the individual case, and it is hoped that the description given may enable any who approve of my suggestion to put it into execution. It should be understood that, in advance of any application of the ligature around the pedicle, the womb should be drawn forcibly upward, so as to put the vagina on the stretch, and at the same time bring the cervix uteri well above the bladder, thus facilitating the division of any adhesions with its wall, which must in all cases precede the incision through the tissues of the vaginal canal.

With this process of ligation around a metallic tube within the cervical or vaginal canal, it will be perceived that the obstruction of the circulation must be more effective than simply encircling the tissues. With a solid body within, the pressure will be secured by the ligature drawing upon the thin layer in contact with the tube throughout the entire circumference of the part enclosed in the loop, and the strangulation being carried to any extent that may be desired before tying the knot, will lead certainly to the detachment of the portion above the ligature within the specified period of six days. The death of this band of tissue is not likely to contaminate the adjacent parts under the use of daily ablutions with carbolized solutions until it is brought away through the tube with the surrounding tape ligature, and no further danger is to be anticipated from any other source.

The inconvenience of securing the pedicle in the external abdominal incision, as in Porro's operation, may be entirely obviated by this mode of treating it; and the embarrassments growing out of Taylor's plan of dropping the ligated pedicle, cannot ensue from this.

In view of the facility thus afforded for a thorough drainage and disinfection, excision of the womb must be freed from risk of septicæmia.

It is claimed that the adoption of this process would have the following advantages:—

1. Security against hemorrhage, primary or secondary, by the constriction of the tissues around the tube.

2. Efficient drainage and disinfection of the cavity.

3. Prevention of subsequent irritation by the removal of all ligatures before completing the cure of the case.

4. Maintaining the pedicle in its natural relation without any tension upon adjoining parts.

5. Closure of external incision by first intention, with the least possible delay.

6. Obviating the ordinary tendency to septicæmia.

If I am correct in attributing to this plan of operating a superiority over other modes of securing the pedicle, it is worthy of adoption.

This suggestion has been presented to the consideration of Mr. Spencer Wells, of London, and to that of Drs. Nathan Bozeman and J. Marion Sims, of New York, each of whom, without any endorsement of the proposed plan, encouraged me to present my view of its advantages to the medical public. In a letter of October 14th, 1880, from Dr. Sims, touching this matter, he remarks, "If a case should occur to me in which I thought your method would answer, I would adopt it, of course." As yet known, there has not been any application of it in the human subject, and it is simply with a view to bring it to the attention of gynecologists and surgeons generally, that this description is given, so that its merits may be tested by trial in some case suited to its use.

INCISED WOUND OF THE ABDOMEN, WITH PROLAPSUS OF THE INTESTINES.*

Translated from the Spanish.

BY AUGUSTIN M. FERNANDEZ, A.B., M.D.,
Of New York.

I. A. Guerra, a colored man, was wounded in the abdomen with a dagger, on the evening of February 20th, 1882, and brought on foot to the House of Emergencies (*Casa de Socorro*, literally, house of succor), of the 4th district of this city (Havana), a distance of about four squares from the place of the assault. The surgeon on duty, Dr. Edwardo F. Plá, gives the following account:—

"I. A. Guerra walked in at about 9 P.M., having a large wound on the right side of the abdomen, which was bleeding profusely, and allowed the passage of a large portion of intestines. The knife had entered the right side of the abdomen, at the anterior extremity of the eleventh intercostal space, its point coming out at the opposite side, one and a half centimeters distant from the synchondro-costal border, there forming an irregular V-shaped wound, the second branch of which had been caused by the sudden withdrawal of the knife; through this aperture there was hanging a piece of epiploon. I examined both wounds carefully, and finding the protruding parts to be intact, replaced them in position, and put nine sutures with thick vegetable (hemp) ligature to the anterior wounds, and two to the posterior one, taking in all the muscular as well as the tegumentary coats. The anterior (*i. e.* the lower) wound was almost horizontal, and of ten centimeters in length."

Diagnosis.—The question of any abdominal viscera being injured was undecided.

Prognosis.—Death.

Treatment.—Besides the proper attention to the wounds, Dr. Plá ordered an opiate, ice water compresses, rest in bed, and absolute abstention from all kinds of food.

February 21st, A.M. The patient is alive, and his strength, voice and intelligence are perfectly normal. He complains of pain in the posterior wound. There is diarrhœa. Pulse and temperature normal. The dressing was removed, and the wounds bled very little. The opiate prescribed by Dr. Plá was ordered to be continued, and the compresses of ice water substitued for compresses wetted with ice-cold "*áqua de la pildora*,"* to which a few drops of laudanum were added. Only small doses of chicken broth allowed as nourishment. Evening of the same day. A little coughing, of no consequence. The diarrhœa continues. Temperature 38° C.

February 22d. Wounds again dressed. No material change. Temperature 37.5° C. This condition continued throughout the night.

February 23d. The pain has disappeared. Four sutures of the anterior wound, and two of the posterior one are cut off. The diarrhœa continues. Temperature 37.2° C.

February 24th. No change. A blood clot,

* This very interesting case was reported in the *Cronica Medico-Quirurgica*, of Havana, Cuba, June, 1882.

* This is an empirical Cuban preparation. It is composed of pure water, to which a few grains of the sub-nitrate of mercury are added. (*Obs. of the translator.*)

which had been forming in the posterior wound, came out. Two more sutures of the anterior wound are cut off. The diarrhœa continues.

February 25th. All continue the same as the day previous.

February 26th. The last sutures are cut off. The anterior wound is almost cicatrized, and the posterior one only lacks union for a distance of about one centimeter in its centre. The diarrhœa has disappeared.

March 3d. No material change has occurred during the four days past. The posterior wound is already cicatrized, and the anterior one only lacks union in its centre.

In the report sent to-day to the civil authority, in whose hands the prosecution of the assailant rests, it is stated that, eleven days having elapsed since the time of the stabbing, there is reason to believe the danger from the most serious complications likely to arise in this class of wounds is passed over.

March 4th. Last night the patient had a severe pain all along the track of the wound. There is a little swelling on the right side of the abdomen. The patient has not had a passage from the bowels for two days. The pulse is natural, temperature 37.4° C. There is no change in the countenance. All these circumstances lead me to suppose there is no danger of any serious complication. I ordered a laxative enema and an opiate. Evening of the same day. I dressed the wound again; the pain along its track continues. The opiate has not yet been sent for, but being got, a dose was at once given in my presence. At the second or third dose the pain was relieved. During the night the patient ejected large quantities of gas and excreta. He must have eaten some solid food, against my positive order not to do so, although he denies it. I desired a consultation to be had, so as to clear my mind in regard to the true cause of this slight complication, but the patient refused it. It was afterwards proved to be a flatulent colic, due, probably, to the nature of some ingesta taken.

March 5th. All continue well.

March 8th. No important change during the last three days. Only about two centimeters' length of the anterior wound lacks cicatrization. The patient is nimble, and feels strong; can walk, and is able to get in and out of his suspended cot.

March 10th. Keloid appears. Cauterization with nitrate of silver, repeated every two days.

March 18th. There is complete cicatrization, and the patient is in perfect health.

Such a remarkable case of incised wound of the abdomen, in which there was no peritonitis, no complication of any account, and complete cicatrization in 26 days, is certainly surprising. The tolerance of the peritoneum to such a terrible traumatic injury is wonderful. It is my opinion, therefore, that a simple record of this case, without any commentary or claim to any especial treatment on my part, is sufficient to justify this hastily written report.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINICAL LECTURE BY ALONZO CLARK, M.D.,

Professor of Pathology and Practical Medicine.

Phthisis.

A male patient, about 35 years of age. In answer to questions the patient states that his trouble is lung or throat disease; that he is short of breath, gets out of breath on going up stairs. He can lie on one side as well as on the other; does not have to elevate the head greatly with pillows. These questions were directed to the possibility of there being heart disease, and we do not make anything very positive about it. Now we turn to the lungs. He says he has a cough which troubles him at all times of the day; he raises greenish matter; not enough to fill a teacup in twenty-four hours. He has never coughed up blood. He says his father died of asthma. He does not remember whether he had a cough or whether he spit up blood. Persons, however, do not usually die in a paroxysm of asthma; the disease goes on and on, paroxysm after paroxysm, and there comes then a chronic bronchitis and an emphysema of the lungs, and they are almost always found to die of some intercurrent affection. The asthma has weakened them very much, they have not the usual power of resistance, and when a disease which they might otherwise have withstood assails them they are likely to sink under it. And the fact that his father had asthma, or at least, as he supposes, he had asthma and died of it, renders it very likely that he may have had phthisis. His mother died at a good age, he thinks of dysentery. None of his brothers or sisters died of phthisis. So we do not make much in the direction of possibility of hereditary phthisis.

He has had this cough for two years, and he thinks it is no worse now than it was a year ago; he has not lost weight, but if anything, thinks he has gained some. So we do not get anything very decided out of the rational signs in this direction. That he has had a cough two years makes it presumptive he has phthisis. He has not spit blood; he has not become more emaciated; these are two facts that are on the contrary side, and we have nothing left but to examine the chest.

Disease of the heart I think is rather excluded by the rational signs, but perhaps not positively. There is scarcely any observable prominence in

the region of the heart, as you will see. You can see a slight impulse of the apex against the chest wall, and there is a more apparent pulsation in the region of the epigastrium. The apex should be three inches and a half from the median line and about an inch below and within the nipple. In this case it is a little too far from the median line, being about three inches and three quarters.

I listen here near the base, to ascertain whether there is a murmur at the aortic opening. The two sounds which I hear here are the first and second sounds of the heart, which are perfectly clear; there is no purr, no prolongation, no unusual sound; the same is true when I listen over the apex; so that we may pretty fairly exclude the heart in our diagnosis, with the exception, perhaps, of a quarter of an inch in size larger than it should be. The size of the heart naturally varies with the breadth of the shoulders. If a man is very wide shouldered he may have a heart a little larger than another who is narrow. This man is about average in that regard, I judge.

Now, we will examine with regard to the lungs, and something strikes me at once, as I expose the chest, that is, a very marked shrinkage of the chest on the right side, at the apex, which is very significant. There is quite a large pit upon the right side which you do not see upon the left. As I listen to the breathing I am to determine two things: first, the tone of the respiratory sound, whether it be exalted or flattened; and second, whether the expiration is altered. In a healthy state of things the expiration should be heard to about one-fifth the length of inspiration. Just as it begins you can hear a little murmur, and then it is extinguished. The inspiration, however, you can hear during all the time of its continuance. If there is anything that makes the expiratory sound longer than it should be, it is some condensation of the lung enabling the tissue of the lung to conduct the sounds which are produced to the surface. Then, if the expiration is longer than the inspiration, or if it be markedly prolonged, there is reason to fear that there is consolidation, from some cause. It may be pneumonia, not fully consolidated; it may be a tumor conducting the sound; but in nineteen cases out of twenty, it is phthisis.

This is a Yankee notion, the value of prolonged expiration in the diagnosis of phthisis. Perhaps some of you may have heard of the reputation and far fame of Dr. James Jackson, of Boston, who lived to a good old age, and was greatly respected throughout New England and wherever he was known. He had a son named James, and after he had completed his college education his father sent him to France and put him under the tuition of Mr. Louis. One day, as he was listening to some patients in charge of Mr. Louis, he observed this prolonged expiration. After a little time he had another opportunity, and he observed this prolonged expiration again, in a phthisical person, and after three or four observations he communicated the fact to Mr. Louis, who had not noticed it before, and nobody had noticed it up to that time. Mr. Louis examined some patients and found it to be a valuable indication of physical changes in the chest, so that it is, as I told you, a Yankee notion, discovered, to be sure, in Paris, but by a person destined to live in America; but he died early, unfortunately.

This prolonged expiration we have here. The next point is to ascertain whether the sound of the voice is longer upon this, the right side, than upon the other. Yes, it is twice as loud here, and the tone is a little different. It is a little higher pitched, and has a great deal more volume. Another point, the amount of vibration which the voice produces upon the two sides. I perceive fully twice as much jar on the right side.

There is another evidence with reference to consolidation. That is, the difference in the percussion note on the two sides. It is considerably higher on the right side than on the left.

I also hear the voice quite distinctly, louder on the shoulder on the right side than on the left. I cannot discover a râle. It is an important thing, however, if you can find it.

The increase of resonance I follow to the lower angle of the scapula, and down here I get a new fact; the voice here seems to be extinguished, or seems to come from a distance. It loses all there is in its volume. Now, the question is, what produces that? The most common thing is a pleuritic effusion. It may be that this is below the lung, and that consequently there should be no voice sound here. I have observed that the extent of the healthy lung below the scapula is equal to the width of my hand with the thumb spread, while in this case the point of dullness is found an inch and a half inside of that distance. We find that this side of the chest in this region does not move as freely as the other when he breathes deeply; the amount of restraint in it, however, is not very considerable; still, what there is is worth noting, as it helps us in the diagnosis. This inch and a half of fluid, this shrinkage of the chest, and the movement less distinct upon this side as compared with the other during respiration, are three facts that point to pleurisy. The pleuritic effusion has been greater than it is now, as is pretty evident from the skrinking. He is nearly over it. The fluid has subsided until there remains only about an inch and a half, in a wedge-like form, made by the chest on one side and the sloping diaphragm on the other. The quantity is really very little, and unless it is confined by adhesions I can show that to you. When he leans over the counter I get the voice sound distinctly down to here, which is nearly two inches below the position at which I get it when he stands. We make out, then, that he has or has had some pleurisy. He says, however, he has not had any pain at any time in the side. So we have no evidence there in favor of pleurisy, but still there is water here. That is demonstrated by the fact that there is dullness on percussion at the same line where the voice seems to be partially extinguished in going from above downward, and from the further fact that the side is shrunken, and also from the fact that it does not move as freely as the other on respiration.

We find, then, that he has evidence of con-

solidation of the lung under the right clavicle, and that it extends downward under the scapula to the inferior angle of that bone; that the voice is about natural below that, until we get down about the width of my hand and a little more, and then the voice is extinguished again and dullness on percussion appears. It disappears when he lies upon his belly and comes again when he assumes the erect position. Then the cough, which has continued for two years, almost invariably; if there is much expectoration associated with phthisis, you get a pretty clean diagnosis; phthisis of the right lung, and pleurisy that is probably consequent upon that disease, but now getting well.

Then the question is, what shall we do for him? The secondary disease, pleurisy, is getting well; it will be safe to leave that to itself. If it were not, then some diuretic would help him. And a favorite one with me is the bicarbonate of soda—it is an old prescription, older than I am, a great deal—carbonate of soda, half an ounce; water, six ounces; a tablespoonful of that with a tablespoonful of fresh lemon juice mixed together and taken every two hours; then add a dessertspoonful of the infusion of digitalis three times a day. In three persons out of four it will produce marked, or at any rate, sufficient diuresis to carry off the fluid of the pleurisy when the inflammation has abated. And if this patient should need anything in that line, that would be as good as anything he could take.

Then, with reference to the phthisis, he must build up his system and maintain his strength as long as he can. Two years and no cavity, is perhaps a favorable condition, and the additional fact that he has not emaciated, or if he has, he has regained what he lost, is worthy of being taken into account in the prognosis. You remember, we did not find any positive evidence of hereditary disease of that kind. His father, as you heard, he thinks died of asthma. That certainly is doubtful; there is a greater chance that it was phthisis than asthma, and if so, then there is an element in the prognosis that is of some importance. Inherited phthisis is not as curable as that which occurs spontaneously in the individual. Yet you will sometimes observe that even those who are hereditarily predisposed to it will recover. The common opinion is that consumption is death, or equivalent to it. But in my own observation hundreds, and I do not know but I might say thousands, have been prescribed for in the early stage of phthisis, and have thrown it off wholly.

The treatment is entirely corroborative. There is no specific, and notwithstanding the many advertisements of waters and medicines that will cure the consumption, there is nothing of any value in any of them. The whole thing consists in three or four very plain and simple facts. First, a free exposure to the open air. An indoor occupation is unfavorable to a favorable result. The person should be out of doors. If he is strong enough, walk out of doors many hours of the day. And one means by which he can occupy his time profitably is by riding on horseback. So long ago as when Sydenham wrote, which is two hundred years, horseback exercise has been famous for its favorable effects upon phthisis. Indeed, Sydenham says that horseback exercise will cure consumption as Jesuit's bark will cure the fever and ague. He is reported to have said that horseback exercise will cure consumption if mercury will cure the French pox, but he did not say it. At least, if he said it, he did not write it in his book.

The value of horseback exercise is very well illustrated in a case I had last spring. A young man was getting worse and worse every week, with phthisis. When February came I told him to go to Aiken, hire a horse by the month, and ride every day, twenty to twenty five miles. Of course he could not do that well the first day, or the second day, or the third, for riding, to a person who is not accustomed to it, produces a good deal of soreness of the muscles. He worked into it, and at length after a week or two he was able to ride the prescribed amount, and within a fortnight he wrote that his cough was cured; that he was gaining strength every day. He continued that for about a month or a little longer, and then was so well that, against advice, he insisted upon coming home. He came home and had no cough for a fortnight, but the cough came on in bad weather of spring again, and he has perhaps gained a little during the summer, but still coughs. He ought to have remained longer and taken his exercise there, as prescribed, for a longer period. But we can hardly prescribe that for this man, for, of course, horseback exercise is not a very cheap entertainment in New York. But he can be in the open air; he can sit in the parks.

The next point is the food; oily food is almost essential. Everybody knows the reputation of cod-liver oil in such cases, but the same kind of food can be obtained in other ways, ways that we might almost call more natural. The cow's milk contains, of course, butter, when it is fresh, and that is an oil favorable to improvement in phthisis. I have everybody that has tubercles of the lungs to drink milk, from one to two quarts a day, and in addition, those who are able to meet the expense, a half a pint of cream in the course of the day. The cream, to most persons, is very acceptable, and is for them a very happy substitute for cod-liver oil. The cream is taken on hominy, oatmeal stir-about, baked apples or peaches, when they are in season, and most people think that it adds to the taste and is a luxury.

Then, in regard to solid food, the most nutritious are the best, and there is none better than beef; roast beef, beef steak. I have not come to the feeding of my patients with raw beef, because it is unpleasant to me, and I do not believe that there is any particular virtue in rawness. But to eat well and to exercise sufficiently to secure good digestion are the main points in that direction.

Then I think some virtue can be found in friction to the surface of the body. I do not use counter irritants, as that word is commonly used; that is, no blisters, no moxas, no setons, but friction with dry flannel to the whole body once, or if convenient, twice a day. The flannel is electrical in dry, cool weather, and perhaps there is something stimulating in that, but at

any rate it seems to be about the best thing for applying friction, and it is to be applied to all parts of the body, excepting the neck and face, where it is inconvenient to apply it. The most convenient time is before one dresses in the morning and when he retires at night. This I urge a good deal.

Then, for medicines, nothing but what the particular symptoms require; that is, if a man has impaired appetite, the compound tincture of gentian, a teaspoonful in a tablespoonful of sherry, will often awaken it. I saw an old lady who was dying of cancer of the liver, some time ago, and I advised that she should take the citrate of iron and quinine in lemonade, and when I saw her the next time she said, "Doctor, what a wonderful medicine that was you prescribed for me last week. Before I took it I could not eat anything, and now I have to call the girl up in the night to give me bread and butter." Several of the tonics act favorably in that way, but perhaps the compound tincture of gentian, or the compound tincture of the bark given in a little wine, will be, in the greater number of cases, the best one. How is your appetite? "It is good." Then he does not need anything to help that.

Doctors are very apt to give cough medicines, but almost any cough medicine that is efficacious contains more or less of opium, and the opium, in about half those who take it, impairs the appetite, in the morning particularly, and perhaps all the day. I prefer, when anything is necessary, an inhalation which does not affect the stomach. The inhalation of steam is a pretty good thing. Have the patient breathe the vapor of water for four or five minutes several times in the course of the day. I do not know that it does anything more than soften the mucus and enable the patient to expectorate it more easily, but it seems to be very good. Then there is another inhalation at my suggestion, where the cough is exaggerated, and by that I mean where it is more than it ought to be for the raising of the amount of material that is secreted in the bronchial tubes. It will do it marvelously sometimes. Dissolve two grains of the extract of opium, which has been dissolved before, in three ounces of water, and if you choose, add a very small quantity of glycerine, have that converted into a spray and breathe into the lungs. The little apparatus, with a bulb that is compressed and makes the spray, can be held by the patient himself and the mouth opened. The moment inspiration begins, he compresses the bulb and the spray is thrown into his mouth, perhaps into his face, some of it, and he breathes it in with his breath about seven or eight times in succession. Perhaps I can enforce the value of that point by referring to a case.

A lady came to town some years ago with her daughter. The daughter may have been twelve years old, and she had a cough that was constant. No expectoration in any amount, but coughing every second breath. She did not cough while asleep; that is, she was not awakened by the cough, and that led me to suppose it was dependent upon nervous excitability more than upon the secretion in the bronchial tubes. She went to a hotel, arriving in the city at eleven o'clock at night, and the next morning she brought her daughter to the table, to breakfast, and the cough continued just as before, and directly there was a person speaking to her, that is, to the mother. He said, "I observe that your daughter has a bad cough. I am a physician, have an office in this hotel, and if you come to me after breakfast, I can prescribe something that will relieve her." She said, "No, I came to the city with the intention of seeing Dr. Clark, and I think I had better keep my purpose." And he urged a little, and when the lady went to her room she found a stranger there, a woman, who introduced herself as Mrs. Dr. So and So, and she came to see if the lady, being a stranger in New York, would be aided in any way in her viewing the city or shopping; she would be very glad to lend her assistance to further the aims of the stranger. And the attention was so pressing she concluded she would go and pay the doctor a visit, as that was the thing aimed at by both the Doctor and the Doctor's wife. And she went, and he prescribed for her, and the next morning the cough was all the same, not modified at all, and she concluded she had better keep her first purpose and come to me. I prescribed for her a medicine, an inhalation that has done a great deal of good in other cases, that is, the tincture of balsam of tolu and Hoffman's anodyne, which is ether as you know, mixed in equal parts, and a few drops put into a warm cup. The exhalation is pretty nearly pure ether and the alcohol, with some of the balsam dissolved in it, and that, breathed a few times, will frequently allay a similar nervous cough. I prescribed that, but it did not do. She came back the next morning and coughed the same. Well, I said, now what invention can I make that will just meet this case? She was very sorry to have the Doctor's ears annoyed every morning at breakfast by this cough. Then the thought of dissolving the extract of opium in water, and administering it as a spray, occurred to me, and I prescribed it. The lady came back to me, and she said, "after my daughter breathed two or three times of that medicine you gave her, she had no cough, and she has had none since." Coughs that are in great degree nervous, that is, a cough that is out of proportion to the occasion of it, will yield to that inhalation frequently and very quickly, and I prescribe it very often.

A lady came to me, for example, with pretty marked signs of phthisis. The cough was urgent and I prescribed this, and in a couple of days she came back to say that she was much better. She was not well, but she felt so much better that she flattered herself that the disease was removed.

In general I say cough medicines are not good. Then with reference to the Churchill remedies: I have not learned to have much faith in them—the hypophosphites—and yet I do very often give them, and have it continued for months—the hypophosphite of lime. I do not know that there is any particular virtue in Fellows' preparation. If you have a good druggist you can rely on him for the choice of medicines. So I prescribe, without naming what preparation, the hypophosphite of lime, five grains three times a day.

Lately a new principle seems to be getting some rational foundation, the inhalation of germicides; the inhalation of medicines that will kill the creatures that make phthisis. Some of you, perhaps, do not know that within the last year, not for the first time, however, there has been brought forward very plausible cases going to show that parasites or germs are the source of irritation which produces phthisis, and only yesterday I heard of a case that seemed to have some significance. A gentleman came to me four years ago, having phthisis, and this was before Cox's discovery, and I advised him to inhale the spray of carbolic acid, one drop to two hundred. He got his apparatus and he began to breathe it, and persisted in it, and in a short time, two or three months, his cough left him, and he has since been well. He came to show himself before me yesterday or the day before, and he ascribed his recovery entirely to the inhalation of that carbolic acid, one to two hundred of water. It is not well to prescribe that unless you have some supervision of it. It is somewhat irritating, and you want the means of reducing the strength of the inhalation if it is irritating, and the patient should call upon you pretty often unless he has gotten pretty well under way of it.

But the greatest thing, after all, is full nutrition, exercise in the open air, and the administration of milk and cream.

Periscope.

Spasmodic Stricture of the Œsophagus.

At a recent meeting of the New York Medical and Surgical Society (*New York Medical Journal, Obst. Rev.*)—Dr. Francis Delafield narrated a case as follows: The patient was an unmarried woman, twenty-three years of age. He saw her first on the 16th of February, 1882, when she stated that she had always enjoyed good health until eighteen months before. At that time she began to suffer from attacks of severe pain, which was referred to the region of the lower end of the œsophagus. These attacks occurred about once a week, lasted ten or fifteen minutes, and had no relation to the taking of food. They sometimes occurred in the night, sometimes in the day. There were no other symptoms whatever. After three months she experienced difficulty in swallowing solids, and subsequently in swallowing liquids. At length she could take no solid food, and liquids could be swallowed only at times. On some days she could swallow nothing whatever. She starved to a certain extent, but had no other symptoms. Menstruation continued regular, and there were no neurotic symptoms. Dr. Delafield was able to pass a large œsophageal tube into the stomach, and he therefore supposed the case was one of spasmodic stricture of the œsophagus, and at first attempted to treat it by passing the bougie every day, under which she seemed to improve for a time only. On some days she could swallow fluids, but oftener she could not, and as she gained nothing in weight she was taught how to introduce half a pint of milk and half a pint of cream, mixed, into the stomach, through the stomach tube, to be repeated once a day. Besides, she was to try to eat regularly. She had done this since the 9th of March, and during all this time had been able to eat solid food at any time in the day, but it was her custom to eat an ordinary meal for breakfast and dinner, and to take the milk and cream, in the manner indicated, in the evening. From her normal weight of 125 pounds she had fallen to 99 pounds, but after adopting this plan she had gained 14 pounds. It was probable, however, that, like some cases of spasmodic stricture which had been reported, this one would continue for a long time.

Dr. R. F. Weir suggested that possibly the stricture might be overcome by over-distention, as in cases of stricture of the rectum or urethra. An œsophageal tube, with a rubber bulb at the lower end, which could be distended with water, might be arranged for the purpose.

Dr. F. N. Otis remarked that a very slight amount of force would sometimes overcome spasmodic stricture of the urethra, and such might perhaps be the case with the œsophagus.

Dr. Delafield thought that in the so-called spasmodic stricture of the œsophagus there was no particular resistance to the passage of the bougie.

Traumatic Injuries of the Liver and Hepatic Abscess.

Dr. W. S. Elkin has made some interesting researches on this subject in the Pathological Laboratory of the University of Pennsylvania, all the results being verified by Dr. Formad, the microscopist to that institution. He reports them in the Atlanta *Medical Register*. He says, "By a series of careful experiments I think I am able to prove that gunshot wounds of the liver, not involving its large vessels, are not fatal, and that they will heal without the development of any serious constitutional symptoms. Furthermore, I will endeavor to show that we can detect in the pus from liver abscesses, liver cells, which fact will be an invaluable diagnostic point.

Gunshot wounds were inflicted on the livers of large dogs, while irritants were resorted to in the cases of small dogs.

In shooting the animals, care was taken not to wound any of the larger blood vessels of the liver, or injure any of the surrounding organs.

To accomplish this, the ball was made to enter the body of the animal between the seventh and eighth or eighth and ninth ribs, and range so as to penetrate the liver and lodge in the muscles of the back, to the right of the spinal column. The size of the cartridge ball was No. 22, long.

Injections were made in the liver, usually, between the seventh and eighth ribs. The hypodermic syringe used for this purpose had, instead of the ordinary short, delicate needle, a large, stout one, two and a half inches long, which could be made to penetrate deep into the liver structure. The irritant used was tincture of cantharides, U. S. P.

The animals were kept alive from ten to twenty-five days. Immediately after the death of the dog the liver was removed and put in dilute, and after twenty-fours, into stronger alcohol.

The results of these experiments demonstrated: 1st. That the injuries of the liver heal in precisely the same manner as external wounds of the body heal. 2d. Hepatic abscesses are not produced from the gunshot wounds of the liver. 3d. Gunshot wounds of the liver do not produce any grave constitutional symptoms, and unless other vital parts are wounded, do not terminate fatally. 4th. The earliest time for healing of injuries of the capsule is five days, and of the true liver structure, fifteen days. 5th. The injection of simple irritating fluids into the substance of the liver produces similar results to those noted above."

As regards liver cells in hepatic abscess, he thinks they have been overlooked, on account of want of proper precautions in looking for them.

"I discovered that the liver cells were extremely pale, and so faintly visible that I was not surprised that I did not detect them at my previous examinations. With a high magnifying power I noticed semi-translucent bodies, frequently containing fat vesicles, and sometimes presenting a milky, faintly granular appearance. Occasionally a group of these translucent bodies were seen together. In no case could I discover these if I took a large drop of pus, so that everything was crowded by leucocytes and granular debris. In minute quantities, however, diluted with a drop of distilled water, the faint irregular bodies referred to became distinct enough to admit of observation. Upon careful study these bodies proved to be liver cells, which had lost their coloring matter from prolonged maceration in the serum. I have convinced myself of the above by scraping some pus from the wall of the abscess of the liver, obtained post-mortem, from this case, and here I could distinctly trace out the gradual transition between perfect liver cells and the faint, macerated-looking bodies which are found in the contents of the abscess, and which are direct derivations from the true liver cells. I regard the occurrence of fat drops in these bodies as a corroborative proof, as it is impossible for any other detached cell to contain fat drops of this character."

In conclusion, he says: "I am confident, from the examinations made by myself, and from the results of those reported by the above authorities, that a careful microscopical examination of the pus from true hepatic abscesses will, in every case, reveal liver cells, and with this fact proven we certainly have an invaluable diagnostic point in cases of hepatic abscesses."

Retained Placenta.

The following instructive case was presented by Dr. T. R. Trotter to the last meeting of the Mississippi State Medical Association :—

I was called to see Mrs. B., February 19th, and upon inquiry, obtained the following history: She was about six and a half months advanced in pregnancy, and had aborted about eight days prior to my visit. The midwife who attended her failed to remove the placenta, assuring the family that it would pass off without any trouble. I learned that she had complained of great distress in the back and hypogastric region, and had more or less fever; the family, however, were resting easy, under the delusion that everything would be right in a few days, and failed to appreciate, until the morning of my visit, the great danger to which she was exposed. Upon attempting to arise from her bed, she was taken with a terrible flooding; I was at once sent for, seven miles, and when I arrived found her very restless, pulse almost imperceptible, extremities cold, and the whole surface bathed in a cold, clammy perspiration, a continuous flow of blood from the vagina, eyes sunken, and the whole countenance denoting the greatest anxiety.

I gave her at once brandy, and had her rubbed with dry mustard, and gave her a large dose of ergot, and attempted to introduce my hand into the uterine cavity to remove the placenta; this I failed to do, on account of its contracted condition. I, however, succeeded in introducing the index finger, and proceeded, as cautiously as possible, to remove a portion of the placenta; the remainder I could not remove because the finger could not be passed around it. The flooding moderated at once, but she was pale as a corpse, and passed from one fainting spell into another for several hours; notwithstanding the frequent administration of brandy, chicken tea, etc. In eight or ten hours she was seized with a severe rigor, great thirst, restlessness, insomnia, and a small, rapid pulse, and complained of soreness and pain in the region of the womb and intense pain in the back, so much so that she could remain in one position but a few moments. I gave her enemas of laudanum for the restlessness and pain, and spirits of nitre and gelseminum for the febrile stage. As soon as the sweating stage set in, I gave quinine, iron and arom. sulph. acid; I continued this treatment about six days; after that I gave quinine, iron and nutritious diet. I used, from the beginning, flannels wrung out of hot water, vinegar and laudanum, alternated with hot turpentine stupes to her bowels, frequently injecting the vagina with a solution of chlorinated soda.

The discharges per vaginam were very offensive, her tongue was very dry and red, and great tympanites and dysuria; to relieve this condition, I gave her turpentine internally and used it externally over the bowels.

About the thirteenth day abscesses were observed about her ankles, which, after being opened, gave issue to very offensive purulent matter. About the sixteenth day she began to

show unmistakable signs of improvement, and in twenty days after my first visit, I considered her out of danger.

This was certainly a very unpromising case, the immense loss of blood, followed by the long continued putrid discharge, toxæmic fever, with its small, thready pulse, great prostration, tympanites, dysuria, and the putrid abscesses, presenting an array of complications sufficient to discourage the most sanguine.

I have reported this case to show what dire calamities ignorance or carelessness on the part of an accoucheur may bring upon an unsuspecting woman, and to impress upon the minds of the young members of the profession the great importance of seeing that every portion of the placenta is removed, and that the uterus is well contracted before leaving the patient.

I would not, however, advise any very prolonged or harsh measures to remove the placenta in cases of abortion prior to the fourth or fifth month, as by so doing the parts may be irritated and her suffering much increased. When the finger cannot be passed around the placenta, I always plug, if I am compelled to leave, and request the family to let me know should anything occur of an alarming character. In twelve to twenty-four hours I always return and remove the plug, and generally find the placenta and a few coagula of blood to come away with it.

The Speed of Thought.

The Boston *Journal of Chemistry* says:—

We have several times given the readers of the *Journal* a report of what has been done by scientists to determine the rate at which nervous influence is transmitted through the telegraphic system of our bodies. Some recent investigations on the subject are thus summed up in the *American Journal of Arts and Sciences*:—

Sensations are transmitted to the brain at a rapidity of about 180 ft. per second, or at one fifth the rate of sound; and this is nearly the same in all individuals.

The brain requires one-tenth of a second to transmit its orders to the nerves which preside over voluntary motion; but this amount varies much in different individuals, and in the same individual at different times, according to the disposition or condition at the time, and is more regular the more sustained the attention.

The time required to transmit an order to the muscles by the motor nerves is nearly the same as that required by the nerves of sensation to pass a sensation; moreover, it passes nearly one hundredth of a second before the muscles are put in motion.

The whole operation requires one and one-fourth to two-tenths of a second. Consequently, when we speak of an active, ardent mind, or of one that is slow, cold, or apathetic, it is not a mere figure of rhetoric, but an absolute and certain fact that such a distinction, with varying gradations, really exists.

The method by which these nerve motions are measured is thus described:—

If a cylinder divided into 360° be caused to rotate 1000 times in a second, it is evident that the passage of one of those degrees before a given point is equal to the 1,360,000th part of a second; this may be divided by a microscope, so that a period of time equaling the ten millionth, or even the one hundred millionth, part of a second may be measured. By this arrangement it is possible to measure the rate of nervous impulse. Suppose an electric shock be given to the arm; it produces a sensation and a contraction of the muscles; then, by noting the interval of time between the shock and the contraction, the time occupied by the action of the brain to produce the contraction, however quick, will be ascertained. By trying this experiment on various parts of the body, the amount of sensibility of the different leading muscles may be determined.

A Difficult Forceps Case.

Dr. John T. Dillon reports the following case in the *British Medical Journal*:—

On May 10th, 1882, at about 10.30 P.M., I was summoned to assist another physician in a midwifery case. The patient, a strong, muscular, well developed country woman, aged 33, was now ill forty-eight hours, in her sixth confinement. All her previous labors were of a most difficult nature, none of her children being born alive; delivery being effected in some cases by forceps and in others by the perforator. The os was fully dilated and the head presenting in the brim of the pelvis, in the first oblique diameter. The waters had been discharged more than twelve hours. There was slight narrowing of the antero posterior diameter. The pains had ceased for some hours, in spite of the use of ergot. There was no constitutional disturbance. Forceps were applied, and after an hour's work the head was delivered, the appearance of which indicated the death of the child. The body could not be extracted. We were about opening the thorax, and eviscerating, when we had recourse to the following novel procedure. We procured about two yards of the ordinary diaper, and this we twisted into a long, narrow fold; and having made a loop, we encircled the child's neck in it. One of us then proceeded to pull on the ends of the fold, while the other, with his hands on the child's head, assisted in the extraction. In a few seconds the body of a large, well nourished child was born. The placenta was pressed out; there was no hemorrhage, and the woman made a rapid recovery. The cord was of the ordinary length and was perfectly normal from the placenta to within five inches of its termination in the umbilicus; here it broke up into a large, spongy mass, closely resembling placental structure. This mass was about the size of a large orange, and from it proceeded, to the navel, something less than one inch of cord, of the ordinary size and appearance. The placenta was normal in every respect.

Abuse of Injections of Morphia.

The *Medical Times and Gazette* says:—

At the first Athens Medical Congress (*Gaz. Méd. d' Orient*, July), Dr. Zambaco terminated a paper upon this subject with these resolutions:—1. Although the subcutaneous injection of

morphia is so precious a means for the relief of pain of all descriptions, patients often contract a habit of using it which it is almost impossible to break through, continuing to employ it after the reason for its use has passed away, and progressively increasing the dose, and inducing a slow poisoning, which acts on nutrition and on the intellectual faculties. 2. Practitioners should prescribe these injections with much precaution, and should not allow the patients to practice them themselves, in order to prevent them contracting the fatal habit. 3. On account of the dangerous effects of their prolonged employment, they should not be used in chronic disease of the heart, in cerebral affections, or in any disease accompanied by debility in general, and especially that of the nervous system. In such cases we may obtain ease advantageously by the hypodermic use of sulphuric ether. 4. The general enthusiasm which at one time gained hold of the profession for these injections has, in face of the calamities that have resulted from their employment, diminished. 5. Although opium acts by its alkaloids, and especially morphia, yet it and its extracts are often preferable to morphia, and it has been an error to so generally displace it. After other speakers had expressed themselves in the same sense, Dr. Galvani said he considered that their observations savored somewhat of exaggeration, and that it would be doing a great injury to medical art to discredit the proper use of these injections, which, like any other remedy, may be abused. Morphinism is especially observed in the great centres of civilization, wherein many have their nervous systems in a condition predisposed for its production. Morphia always requires to be administered with caution, and in relation to the idiosyncrasies of the recipients.

On a Peculiar Reducing Substance in the Urine, from the Internal Employment of Turpentine.

The *Med. Times and Gaz.* says: From the researches of M. Vetlesen, in the Physiological Institute of Christiana, published in the *Nordiskt Medicinskt Arkiv*, for 1882, it appears that during the internal employment of turpentine, the urine contains a rather large quantity of a reducing substance, which, in its reactions (such as blackening, on boiling, an alkaline solution of oxide of bismuth, and reducing the peroxide of copper to the suboxide), seems to be composed in great part of a matter strongly resembling grape-sugar, without, however, being in any way identical with it. The author, in fact, has never succeeded with the polarizing apparatus in observing the rotation to the right side. The reaction disappears after fermentation, which process appears to act more slowly. Experiments subsequently showed that a small quantity of hydrochloric acid destroyed this reducing substance, even at a relatively low temperature, while under the same circumstances it was proved that grape-sugar is only slightly destroyed. The reducing substance described by M. Vetlesen is, in all probability, optically indifferent; it disappears by fermentation with rather more difficulty than grape-sugar; but as it does so when the urine is simply left to rest for about five days, it might perhaps be supposed that it is not a fermentable body. But M. Otto has traced in one experiment, and after fermentation, some alcohol in the distilled product, while before fermentation the urine gave only a negative result. It may be admitted, as the result of the experiment, that the substance appearing in the urine during the internal use of turpentine is a kind of fermentable sugar, the nature of which, however, is not yet specially determined. The researches made appear to show that the quantity of this reducing substance is in relation to the amount of the dose of turpentine, and that it diminishes if the use of this drug be continued for a certain time.

Excision of Superior Maxillary and Inferior Dental Nerves, for Neuralgia.

In the Pittsburgh *Medical Journal*, Dr. Wm. Wallace says: "The fact that a new connecting medium sufficient to enable a nerve to perform its functions can be developed to the extent of an inch or more has been sufficiently attested. Any resection, therefore, which would embrace a less portion of nerve would in all probability be of only temporary benefit, unless the period of relief gained thereby would permit of such constitutional recuperation as would withstand any future attacks.

"My experience in the operation of resection for neuralgia has been extremely limited, but the success attending my efforts has been so satisfactory that I venture to offer it as an inducement for a more extended application of this method of relief."

A severe case of neuralgia coming under his care, it was decided to resect a portion of the inferior dental nerve. The disc of bone removed by the trephine failed to expose the nerve, and the patient bearing ether badly, it was decided to postpone further operative interference. Subsequently, both the superior maxillary and inferior dental nerves were excised.

The continuance of the pain for a few days after the operations and its return for a short time, seven months later, cannot well be accounted for. The clinical features of the case embraced all of the symptoms described by Trousseau as characteristic of epileptiform neuralgia, which he believed to be an expression of true epilepsy, a view scarcely confirmed by the history narrated. Entire and permanent immunity from pain, return of appetite, ability to take solid food and comfortable sleep, were secured by the operations.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The "Transactions" of the Mississippi State Medical Association for its last meeting are very interesting. There are many short articles of much practical value, and the whole is well worth reading.

——An interesting history of the psycho-physical training of an idiotic child is narrated by Dr C. H. S. Davis, of Meriden, Conn., in a reprint from the New England *Medical Monthly*.

——We have received the "Transactions of the State Medical Society, of Arkansas," at its Seventh Annual Session. It contains many good articles, and evidences zealous interest on the part of the profession of the State.

——"The Sixth Annual Report of the State Board of Health, of Wisconsin" (1881), contains a deal of valuable reading. The various articles on hygiene show the increasing interest that is being taken in this science in our country, and many of the articles are of immense practical value.

——Messrs. Lindsay & Blakiston's "Physicians' Visiting List" for 1883 has appeared, in its customary make-up, to which are added the metric system, posological and toxical tables. As this list has been familiar to physicians for thirty years, and always popular, we need not reiterate our often expressed opinion of its merits.

——A valuable point in practice is set forth by Dr. Charles Turnbull, in a reprint from the *Transactions* of the Penna. State Medical Society, entitled "Powdered Boracic Acid in the Treatment of Chronic Purulent Inflammation of the Middle Ear." Copies of it may be had from the author, 1702 Chestnut St., Philadelphia, and it will repay every practitioner to peruse it.

——The importance of "Subjective Traumatism of the Eye" is presented by Dr. W. S. Little, of this city, in a recent reprint. By "Subjective Traumatism," he means the diminution of sight, and diseased condition of the tissues of the organ, resulting from optical defects or ametropia. A number of cases are detailed, with useful suggestions for treatment.

——In a reprint from the Gynecological Society *Transactions*, Dr. W. R. Gillette urges the value of digital assistance during the first stage of labor. He believes that he can, by so doing, dispense with ergot altogether and reduce the use of the forceps very materially. The procedure is very simple. An anæsthetic is administered to the obstetrical degree, that is, just to the extent of dulling the pains; then, *during uterine contraction*, he introduces two fingers into the os and expands them; or by hooking the forefinger on to the cervix, makes firm pressure, occasionally sweeping the finger around the whole cervical orbit. This is done *during the pain and without any violence.*

BOOK NOTICES.

Medical Electricity. A Practical Treatise on the Application of Electricity to Medicine and Surgery. By Roberts Bartholow, A.M., M.D., etc. Second edition, enlarged, with 109 illustrations. Philadelphia: H. C. Lea's Son & Co. 1882. Cloth, pp. 286.

It is safe to say that in the minds of most physicians there is a certain degree of haziness about the use of electricity in medicine. They probably own a battery, and if they have had it two years, it is probably out of order; they can recall some cases where this mysterious agent seemed to work wonders, and a good many more where it utterly failed. Why it did either, they don't know.

Yet there is no doubt but that its therapeutic use is increasing. This work of Dr. Bartholow's will, therefore, be welcome to many. It is fortunately not such an interminable treatise as most electro-therapeutists like to write. It is not burdened with a needlessly learned terminology, and is written more from the point of view of the physician than the specialist. The second edition has been considerably increased over the first, and has been brought up to the most recent advances of the science. It can in every way be recommended to those who wish to read a lucid, manageable monograph on this form of therapeutics.

On Slight Ailments; their Nature and Treatment. By Lionel S. Beale, M.B., F.R.S. Second edition, enlarged and illustrated. Philadelphia: P. Blakiston, Son & Co., 1882. Cloth, 8vo, pp. 283. Price $1.25.

Obsta principiis is a very wise old maxim in medicine, and Dr. Beale has done an acceptable service in calling the attention of the profession to the often underrated importance of the slighter forms of disease. Let these be neglected, and they often lead to the most serious results; let them be promptly and intelligently attended to, and many a person of feeble constitution will survive to old age in comparative comfort. Dr. Beale discusses such topics as nausea, indigestion, constipation, diarrhœa, worms, vertigo, biliousness, neuralgia, and the common forms of slight inflammation. His suggestions are eminently judicious, and though what he says may be familiar to all members of the profession, their application of the knowledge cannot but be improved by a perusal of his words.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE PROBLEM OF MEDICAL EDUCATION.

A recent issue of the *Lancet*, commenting on the questions involved in medical reform, says: "In plain terms, the history of medical reform in the last fourteen years has been a history of failure; a history of nineteen bodies out of sympathy with the profession, several of which are superfluous, striving to perpetuate themselves and all their individual privileges, without reference to public advantage and the question of justice to those on whom exacting examinations and fees are required."

Thus has the cry ever arisen, of imperfections in medical education, and thus, we are inclined to think, will we continue to hear such wailings, to the end of time. No profession, no human institution, nothing in this sphere is perfect, and without absolute perfection there will ever be room for fault-finding.

The more intelligent public, as well as the better class of physicians, have always been ready to recognize the shortcomings in medical education, and to leave no effort untried to remedy them.

But there is one point little touched upon, and against which legislation can have no influence, namely, the post-graduate education of the physician.

We have in our own country several institutions of medical instruction in which the course of medical training is very satisfactory; not, indeed, all that idealism would require, but still very excellent, and good enough, were it supplemented by the practices of which we are about to speak.

It would be unreasonable to consider a young man just out of a medical college, or but just licensed by an examining board, as a *physician*, in the comprehensive sense of the word.

True, he has received the legal right to practice the healing art, and his possession of a certificate from a recognized institution or a legally constituted body is proof presumptive of his theoretical mastery of the science. But does this make him a physician? Not at all.

He may, and indeed must (if he emerges from one of the institutions we have referred to), have had some practical acquaintance with the clinical aspects of his profession; but this has been so comparatively limited, his time has been so much occupied in laying the solid foundation, that it does not count for much.

In truth, when a young man graduates in medicine he is just ready to commence the serious study of the science; all his college labor has been but a preparation for the real intellectual work that succeeds it.

This labor cannot be controlled by legislation, but is always under the direct influence of inclination or circumstances.

In our country the young men who choose medicine for a profession are, as a rule, strange as it may seem, very deficient in worldly wealth, hence they are compelled to turn their diplomas into practical value as soon as possible.

Among the more favored class, who possess an abundance of pecuniary comfort, disinclination for study is an American characteristic, but it is from among the few sensible and appreciative

ones of this latter class that the leaders of our profession are formed.

A significant fact in this connection is, that in England as well as in our own country, the most learned and scientific physicians have not always been the *best* college students (indeed, in many instances, the case has been just the reverse), thus conclusively demonstrating that the preliminary education is not the all important element of subsequent proficiency.

It is too utopian to hope for perfection in any course of teaching where there is inter-dependence of teacher and taught, and it is practically impossible to *entirely* do away with this condition, since the dependence of one on another, in all walks of life, is the necessary foundation of social existence.

The State may subsidize, but influences and personal considerations will be potent all the same. To a certain extent, selfish motives may be debarred from the regulations for preliminary medical as well as any other education, but its entire eradication, we fear, is an impossibility.

We have certain standard text-books on all the varied branches pertaining to our comprehensive science.

All of our best institutions furnish facilities for bedside instruction and for practical laboratory work.

When a thorough study of the first, and a faithful attendance upon the second is enforced and supplemented by a rigid examination, all that can be done has been done.

Still the successful student is not yet a physician.

Moral suasion is now the all powerful lever that must be called into action to carry on that which has but just been commenced.

The teacher must constantly impress upon his students the all important fact that constant and unremitting study is absolutely necessary if they desire to be physicians in fact and not merely in name. Each member of our profession must ever remember that our science is not like arithmetic, in which certain rules, once committed to memory, will forever remain and serve every purpose.

They must realize that our profession is a progressive and changing one, that not a single day passes in which some new contribution is not made to our voluminous knowledge, and so realizing, they must feel the necessity for constant study.

Again, after we leave the few fundamental principles taught by anatomy, physiology, and pathology, we must remember that ours is not a science of absolute facts, but rather one of broad generalities, and that, therefore, the physician must, preëminently, be a man who cultivates the two faculties of observation and reasoning to their fullest possible extent.

Can any legislation force a man to so regard his post-graduate life? We fear not.

It would therefore seem that the true solution of the problem of "Higher Medical Education" is to be found, *not so much* in legal enactments or other provisions for elevating the requirements of medical schools or licensing boards (though these are all admirable, as far as they go, and form an important part of the whole), as in advice, constant, never ceasing advice, to students and graduates, to persistently and intelligently study throughout life. To build upon the ante-graduate foundation a post-graduate superstructure of broad observation and reasoning, of reading and reflection, that alone can form a temple grand enough to become the abiding place of a *true* physician.

How to erect this structure of post-graduate life should form a more important part, than it now does, of the teachings of our medical instructors.

The post-graduate courses of our best institutions afford certain facilities to those desirous of pursuing their preliminary studies, but these only go to a certain extent, and have an ending, while the student life of a true physician should terminate only with his death; and such a life must be a voluntary one; no force can compel it; advice only can demonstrate its value, and thus secure it accomplishment.

The Louisville *Medical News*, speaking of the late Dr. George B. Winston, of St. Louis, tells us that a friend once remarked to

him, "Doctor, what necessity is there for this ceaseless labor and study at your time of life?" With a look of astonishment never to be forgotten, he replied, "My dear sir, I am under bonds to do it. When I offered my professional services to this community there was an implied covenant on my part that, so far as God gave me strength and ability, I would use them for gathering up and digesting all that has been said or written in regard to the diseases to which human flesh is heir; and if I should lose a patient because of my ignorance of the latest and best experience of others in the treatment of a given case, a just God will hold me responsible for the loss, through inexcusable ignorance, of a precious human life, and punish me accordingly; and whenever I get my consent to be content with present professional attainments, and trust my own personal experience for success, I will withdraw from practice and step from under a weight of honorable obligations which, with my best endeavors to meet them honestly and conscientiously, still sometimes is almost heavier than I can bear."

Dr. Winston's life and example will do more, if conscientiously followed, to solve for us the vexed problem of "Higher Medical Education," than many treatises and much legislation can possibly hope to accomplish.

PROFESSIONAL ETIQUTTE.

We fear this is one of the lost arts among many of our profession. What it means, what are its mandates, what it obliges us to do, no one can plead ignorance of, simply because every decent and respectable man has within his innermost self that little monitor constantly advising him to do unto others as he would that they should do unto him. This, after all, is the foundation of etiquette and of justice in every profession and in every walk of life. There are some men whose moral sense seems so little developed that they fail to realize when they transgress this golden rule, and for such, one can but have pity, and charitably say, forgive them, for they know not what they do. But the majority of our profession have sufficient intelligence, education and innate refinement to cause them to thoroughly appreciate their own littleness and meanness when they degrade themselves to try and secure their own preferment by belittling those whom they feel are too noble and too much above their dirty level to meet them with their own soiled weapons. Feeling this, many conscienceless men are ever ready to aggressively and remorselessly assail others, and to, so to speak, stab them in the dark, trusting that they will never recognize their supposed disguised and ought to be despised assailants.

There is another class of professional parasites, who, while they do not desire to injure their brethren, yet are so constituted, and possess such a small mental calibre, that they cannot resist the temptation to, vulture-like, pounce down upon any imagined weakness or failing in their confrères, and by distorting and magnifying it into gigantic proportions, hope to raise themselves by the supposed thrust downward they have given to some worthy and innocent man. There are so many open questions in medicine, and so many important questions upon which men of equally great eminence entertain directly divergent views, that it is not difficult for one so disposed to criticise almost any statement that may be made or any action that may be performed, and to cite good authority to support his criticism, lacking, the while, the candor or honesty to admit that he whom he criticises can produce equally strong authority for his statements. Such miserably mean men always come to grief in the long run, for be it said, to the credit of human nature, man, on the whole, realizes that honesty is the best policy; and though water for a time may be forced up grade, yet when left to itself it must, according to nature's inevitable laws, seek its level; so these men are ultimately detected in their nefarious attempts at self advancement, and are forced, by public and private opinion, to occupy that low level to which all kinds of dregs, animal and vegetable, naturally belong.

So, then, it is pleasing to the honesty of every right-minded man when such despicable men, (for we can call them by no more gentle name)

are exposed. Such has been recently done in England, in the case of two professional backbiters. In the one case a surgeon was engaged to attend a case of compound fracture. When the man was discharged, cured, the physician presented a bill for sixty dollars. Instead of paying it, the patient, *acting under the advice of another physician*, instituted a suit for damages, on the ground of malpractice, basing his claim on "forgetfulness or ignorance of all the rules of art, and in particular on the employment of perchloride of iron to arrest hemorrhage." A committee of experts, composed of medical men, appointed by the court, concluded in favor of the surgeon; the man offered to pay the bill and withdraw his suit; to this the surgeon objected, when it was ruled by the court that the man should pay the original bill, all costs and one hundred dollars damages to the surgeon. In the second case both plaintiff and defendant were medical men. An illiterate man was sent to a certain city, with a card from a doctor in a neighboring town, recommending him to the care of Dr. A. An omnibus driver, by mistake, took him to the house of Dr. B, who kept both card and patient. Dr. A heard of the occurrence, and meeting Dr. B on the street, upbraided him with his unprofessional conduct, and called him offensive names. B, seeing that his position was compromised, summoned A before the courts, where the tables were entirely turned; B, was condemned to pay A $1000, damages, and an appeal resulted in a confirmation of the judgment.

Such cases should delight every honest man and every reputable practitioner should constitute himself a detective to bring to the bar of justice and purge from the list and companionship of respectable physicians, all who endeavor to advance themselves by libeling honest and capable members of our profession.

It is hard enough for a man to succeed in this world of struggling, even though he receives fair treatment from all, but when the miserable backbiter comes in to injure him his lot is truly deplorable. So then let us have done with unseemly contention in our great profession.

SPURIOUS MEDICAL JOURNALS.

It is common to deplore the fact of the increase of medical colleges and journals in this country. As for the colleges, we expressed ourselves about them recently, and share in the general regret at the formation of so many hurtful institutions.

With journals it is in a measure the same. Pliny is recorded as having said that no book was so utterly weak that he could not learn something useful from it. It would puzzle him, now-a-days, to get anything worth knowing from a good many works which see the light. But it may fairly be said that in scientific literature his remark holds good. Only there the difficulty comes in—and it is a very grave one—to distinguish between what is said for the good of science, and what for the good of self under the mask of science.

There are two classes of medical journals which ought to be weeded out. They are Canada thistles on the soil of professional culture; noxious plants, actively injurious, both by occupying the place of something better, and disseminating poison instead of food.

One of these is the class which sells itself, which levies blackmail, which publishes articles professedly scientific, but secretly intended to cry up or cry down this remedy or that man, this mode of cure or that institution. Does any one say that this species of vermin does not exist among us? To such flattering optimist we answer that within this year we have had submitted to us indisputable legal evidence, where a physician of some general repute and a medical journal that claims a high position had deliberately sold out their pen and pages for a sum of money. They had actually made overtures to both sides and took the highest bidder! This we know, and there are other instances which, as the boys say, we should like to bet on.

All will agree that this species of journals is as noxious a breed as tree worms in autumn, and deserves to be stamped out with as little remorse. About the next class we may not obtain so unanimous a verdict.

These are the journals published as advertising

mediums by drug manufacturers. By the very nature of these periodicals, they cannot be honest. They might be, indeed, if they pretended to be nothing more than what they are, to wit, a tradesman's announcement. But with this they are not content. They assume a learned title, and pretend to be scientific sheets. Of course, they contain a good deal in favor of the drugs they are intended to advertise, and nothing against them. Reports of successful cases attributable to these remedies are eagerly printed, but reports of another color are not wanted. Various arts are used to blind the reader as to their real purpose, and the journal is offered at a very low price, or often given away.

We do not have to go outside of Philadelphia for examples of these spurious, pseudo-scientific sheets. As they are essentially, and by the condition of their existence, one-sided and deceptive, we believe them to be an actual injury to the professional reader. We would warn him that when he sees a lot of letters and statements advocating a drug or preparation, he may be sure that he has in his hands a journal which is merely a trader's advertisement, no matter how it is named. If he doubts it, let him write an adverse criticism on the drug in question, and see if his lines are admitted.

To our mind it would be better if the profession itself drew an authoritative distinction between medical journals which are such, and those which only pretend to the name.

Notes and Comments.

Destruction of Trichinæ.

The *Med. Times and Gaz.* says that M. Fourment's experiments conclusively prove that salting of meats cannot be regarded as a safeguard against trichinosis. He succeeded in producing trichinæ in mice fed upon salted meat that had been again imbedded in fine salt and hermetically sealed for fifteen months. Trichinæ may die in salted meats as well as anywhere else, hence some experimenters have claimed a destructive action for the salt. But the parasites may also live a considerable time without our being able to determine the length of the period after which death necessarily follows latent life. It is also pointed out that when the trichinæ penetrate the muscles, they are perfectly free, and have no covering whatever to protect them, and a month or more elapses before they accept the situation, and coil themselves up to quietly await their chance of being eaten up by some other animal, which must occur before they can possibly develop into the perfect adult condition. But it is only at the end of three months that a fibrous cyst begins to form around them, and it is perhaps a year before the covering is sufficiently dense and impermeable to entirely protect it from the action of salt. The principal safeguard against trichinosis must still be looked for in perfect cooking. In no single case, and numerous experiments have been made, has heat failed to entirely destroy these parasites; and only those who neglect the precaution of thorough cooking (absolutely necessary in the case of all pig-meat and sausages), need be under any fear of their introduction into the system.

Psychosis and Uræmia.

That sometimes severe *psychic* disturbances take place during or following a *uræmic* attack has more than once been alluded to. We are told of a very interesting case, in the *Deutsche Medizinal-Zeitung* of August 3d, 1882, which happened in the large Charité Hospital of Berlin. The case is described in full by Dr. L. Brieger, in the annals of that hospital for 1882.

A man 54 years old, who had for a long time suffered from a kidney disease, was suddenly seized with a number of uræmic attacks. One of them was especially severe and was followed by coma and stertor, lasting twenty-four hours. The urine, which during this state was withdrawn by the catheter, had a dark-red color and was almost stiff, from the presence of a large amount of albumen. Hitherto the urine had shown at times only, and then sparingly, albumen. When the patient at last awoke from his coma he appeared confused. Very soon a state of intense excitement set in, followed by wild hallucinations, which continued uninterruptedly for eighteen hours. Consciousness then gradually returned and reason resumed its sway, but the memory during the time of the attack, and for everything that happened in it, was totally extinguished. During the next four days a plain and well-expressed aphasia could be noted. The presence of the albumen continued in the high degree for a short time still, then it gradually returned to its former moderate percentage.

The patient had a few more light spasmodic attacks, and then became convalescent in so far, as without further symptoms only a mild albuminuria affected him, so that he could be discharged from the hospital.

Subinvolution of the Uterus.

Dr. John Williams delivered an address on this subject before the Section of Obstetric Medicine, at the recent meeting of the British Medical Association (*British Medical Journal*), in which he said that the causes of subinvolution are, general debility; multiparity at an advanced age; post-partum hemorrhage; retention of portions of placenta and membranes; lacerations of the perineum; and pelvic inflammations. Its results are hemorrhage, dysmenorrhœa and prolapsus. Some of these causes, as post-partum hemorrhage, perineal laceration, pelvic inflammation, retention of portions of placenta and membranes, can in a great degree be prevented. Wounds of the perineum should be immediately and completely closed. It is very important to remove the discharges from uterus and vagina, to be effected by abundant hot vaginal injections (three or four pints; temperature 110°–115°) commenced immediately after delivery and repeated twice a day at least. They should contain a disinfectant.

The Action of Hyoscin on the Insane.

In the *Charité Annalen*, of Berlin, 1882, we find the result of very numerous observations which were made by Dr. R. Gnauck, in regard to the effect of *hyoscin* on the insane, of which we made mention in a late number of this journal. G. made use, in these experiments, of the hydro-iodide of hyoscin. He employed it subcutaneously, in the doses of 0.0005 (about $\frac{1}{120}$ grain)–0.0015, or internally in a dose $\frac{2}{3}$ to 1 time as large. The highest subcutaneous dose he ever administered was 0.002, about $\frac{1}{30}$ grain, by which we can see how powerful the remedy is. The results were as follows. Hyoscin has no specific effect whatever on any form of disease of the insane. It causes sleep and removes restlessness, but by no means better than the other known remedies. Toxic side effects (general malaise, headache, vertigo, debility, feeling of being paralyzed, nausea, loss of appetite, etc)., indicate special caution, as the individual sensitiveness to the influence of hyoscin is a very varying one. Generally it is not well received; especially, however, harmful in dementia paralytica and in delirium tremens. An anodyne effect G. had never occasion to note. It can, therefore, perhaps, only be indicated when the other hypnotics seem to have no effect; but in general it cannot be recommended. We draw the attention of our readers who may feel inclined to experiment with this powerful remedy, once more to the fact that it is, perhaps, the most dangerous of all our drugs which have ever been used internally, as the one-hundredth grain of hyoscin has been known to almost cause death. Morphia and stimulation would be the proper antidotes.

Coffee and its Effects.

Dr. P. A. Wilhite read a paper with this title before the last meeting of the South Carolina Medical Association (*Transactions*) in which, after reciting the usual poisonous properties of coffee, he claims that it is more injurious than is generally supposed by the laity or admitted by the profession. He believes that strong coffee, when used to excess, will at least promote, if not cause gout; and its continued use seriously impair the blood, irritate the kidneys, congest the liver, derange the nervous system, and paralyze the digestive functions in all their actions, causing acidity, heartburn, tremor, debility, irritability, dejection of spirits, etc. His attention was directed in an especial manner to these poisonous properties during the late war, when women for whom he had frequently prescribed for a complication of nervous troubles, being unable to procure coffee, became comparatively strong and healthy before the close of the war. He considers that is not so much the quantity taken, as the peculiar susceptibility of some persons to its influence.

A Proposed Substitute for Carbolic Spray.

Dr. A. W. Mayo Robson read a paper on this subject in the Section of Surgery, at the recent meeting of the British Medical Association (*British Medical Journal*). He pointed out the dangers and bad results of the irritating effects of the carbolic spray, and then described his substitute, which he has used in many cases with excellent results. Air is first passed through a cylinder containing cotton-wool, which Pasteur has proved to be sufficient to free it from germs; but as this would only be a pure and not an antiseptic air, it is then passed through two cylinders containing pumice-stone, over which about an ounce of eucalyptol has been poured. Thus it emerges as a pure air,

loaded with invisible particles of an antiseptic, which seems to be capable of destroying any vestiges of germ-life which may have been drawn in from the surrounding atmosphere; it is directed over the desired spot by means of five coralline nozzles, which act on a ball and socket-joint, capable of being fixed in a certain direction by a screw. If in an institution, such as a large hospital, the hydraulic bellows used to work the organ, or the water power used for the lift, can be made available, it would be an easy matter to have a pipe to each ward and to the operating room, which would convey the desired current, ready to be attached to the machine whenever it might be wanted.

Caput Obstipum.

The *Obstetric Gazette* says that Prof. Albert, of Vienna, recently exhibited a child with this affection. The head is inclined to the left; that is, the lateral plane is abnormally near the left shoulder. This condition is usually congenital, and is due generally to peculiarities of the position of the fœtus in utero, allowing contraction of the sterno-cleido-mastoid muscle. In breech presentations and difficult forceps delivery, a laceration of this muscle may occur, with consecutive inflammation and contraction. A mere restitution of the head is of no use; the shortening of the muscles must be counteracted by subcutaneous division, followed by orthopedic treatment.

During the first four or five days the patient must lie upon a hard bed, with the head in a horizontal position. When the soreness has passed away put on the Dieffenbach cravat, which is so firm and high on the affected side as to prevent a return to the faulty position. Acquired caput obstipum may be spastic or paralytic, or the result of cicatricial tissue building, or originate in changes in the spinal column.

Milk Powder in Gastric Affections.

The *Medical Times and Gazette* says that Dr. Debove, in a communication to the Paris Hospital Medical Society (*Gaz. Hebdomadaire*, August 25), observes that the milk regimen, which is so indispensable in affections of the stomach, and especially simple ulcer, speedily becomes so disgusting to these patients that it has to be left off. This serious inconvenience, however, may be remedied by the employment of the œsophageal tube now used for feeding phthisical patients. But by this only a litre of milk can be introduced at a time, so that it would require to be employed six times in order to introduce the six litres, which is the mean quantity required for the subjects of *ulcus rotundum*. To avoid this frequent introduction of the tube, Dr. Debove has had skimmed milk evaporated (cream being but slightly digestible), and the residue reduced to a fine powder. If this be dissolved in warm hot water, two or three litres of milk may be injected in the same volume as a single litre. It is possible that this milk-powder, which furnishes excellent results in gastric affections, may also prove very useful in Bright's disease, cardiac affections, and all cases in which a milk regimen is employed. About a litre of pure milk is represented by 4 ounces of the powder. Dr. Dujardin-Beaumetz observed that in feeding the subjects of phthisis with the tube he has obtained excellent results from a mixture of powder of meat, powder of blood, and powder of milk. As powder of blood is not very digestible, he only adds a small proportion of that as a ferruginous principle.

Sudamina in Typhoid.

M. Albert Robin has found, according to the *Lancet*, that the liquid of typhoid sudamina contains a number of fine globules of fat and some epidermic cells. It contained neither albumen nor sugar, and was not rendered opaque by the addition of alcohol. No uric acid could be discovered in it by the murexide test. An analysis showed that it contained a considerable quantity of chlorides, but no trace of sulphates or phosphates; the proportion of water was 982, of solid matter 18, per 1000; the solids consisting of 14 parts of organic and 4 of inorganic substances. Hence the amount of organic material eliminated by the perspiration in typhoid must be regarded as considerable.

Hyaline Degeneration.

The *Lancet* says that, in *Virchow's Archiv.*, Dr. Max Vallatt describes the process of hyaline or fibrinous degeneration of tubercular formations. In tubercles it is best observed in those which occur in the spleen, lymphatic glands and liver, and is to be regarded as an early stage of caseous degeneration. He concludes that it is formed from the reticulum of the peripheral zone of the tubercles, and also from the trabecular tissue of the spleen and lymphatic glands, the bands becoming thickened, homogeneous and glistening, while the spaces between the original

fibres become converted into narrow channels, in which only the nuclei of the cells that formerly existed there remain. In the tubercle it also replaces the epithelioid and giant cells, the former appearing to be converted into homogeneous non-nucleated masses. The precise share taken by the giant cells in the formation is unknown. The channels left between the degenerated and swollen bands allow of the passage of fluid and pigment particles into the interior of the tubercle. In caseating the material breaks up into a finely granular mass, and is often found to be beset with nuclei, either the relics of previously existing cells or immigrants from surrounding vessels.

Dreams.

The *British Med. Jour.* records some interesting experiments on this subject that have been made by M. G. Delaunay. According to psychologists, dreams are generally illogical and absurd. M. Delaunay, however, by covering his forehead with a layer of cotton wool, rendered at will his dreams healthy and intelligent. According to his experience, the dreams which people have when lying on their back are sensuous, agitated and erotic. Those which occur when the dreamer is lying on the right side are changeable, full of exaggeration, absurd, and relate to old recollections. Those which occur when lying on the left side are intelligent, reasonable and relate to recent occurrences. People often talk during the last mentioned dreams. The author considers that dreams, intelligent or otherwise, erotic or sober, can be induced by causing variations in the cerebral circulation and the nutrition of the various regions of the brain, either by the elevation of the cranial temperature or by decubitus. They, therefore, form an interesting field for psychological research.

Tuberculosis of the Tongue.

The *Lancet* says that Dr. Thomayer, of Prague, describes three cases. In one case a wide fissure existed, about the middle of the dorsum, with yellow-coated base, and prominent, coarse tubercular nodules at its margins. In the second, the ulcer occupied the right half of the tip of the tongue, and in the third it was situated on the frænum. Two of these cases died, and microscopical examination was made. The ulceration had destroyed the mucous membrane and sub-mucous tissue, and the base was formed by a thick layer of small, round cells, intersected here and there by muscular bundles. Beneath this there spread into the inter-muscular spaces masses of similar cells, which were found to consist partly of giant cells and to be separated by the delicate stroma of tubercle. The muscular fibres themselves seemed invaded by the cell growth. The extent of the lesion demonstrates the futility of caustics, and points to excision as the proper treatment.

Treatment of Eclampsia.

Dr. C. Breuss (*Arch. f. Gyn.* xix, p. 218), recommends, for the cure of eclampsia, a strong diaphoresis, produced by hot baths followed by wrapping up in flannels. He has made use of the same, not only during the delivery, but also during the last months of pregnancy, and with success. Pregnancy was in no case interrupted by it, but œdema and albumen in the urine disappeared totally. The baths were kept at a temperature of 40–45° C. The duration of the bath was half an hour; the patients were kept wrapped up in blankets after the baths for two to three hours. The same cure was also employed in hydropic pregnant women affected with albuminuria; and here also the result was such a favorable one, without ever interrupting the normal progress of pregnancy, that we may well recommend future trials of the same.

Aconite.

The *British Medical Journal* says that Mr. E. M. Holmes has drawn the attention of the Pharmaceutical Conference (*Pharm. Jour. and Trans.*,) to the want of uniformity in the root sold as aconite. Many species, or varieties, of the root are current in commerce. Since aconite is now being largely used, internally, in the treatment of inflammatory affections of the lungs, fevers, and other acute cases, it has become extremely important that so powerful an agent should receive far more attention at the hands of the pharmacist than it has hitherto received. We are glad to see that attention has been drawn, by so excellent an authority, to this subject.

Mental Activity and Tissue Metamorphosis.

The London *Medical Record*, quoting from *Archiv. für Pathol. und Pharm.*, says that, after numerous experiments on himself and others, Spick concludes that mental work does not to any perceptible degree affect the metamorphosis of the tissues of the body. The total

quantity of the urine is not altered, nor are the urea, uric acids, chlorides, or sulphates increased or diminished. Contrary to expectation, there is not the slightest increase in the excreted phosphates. The proportion also of oxygen, nitrogen, and carbonic acid in the respired air, is much the same as when the brain is not actively engaged. The molecular changes which occur in the brain during its activity are, therefore, either not oxidation-processes, or, if so, are so little in amount as to escape detection by the methods of investigation employed.

Placenta Prævia.

Dr. John Reid reports a case of placenta prævia, in the *British Medical Journal*, which terminated rather differently from what is generally supposed to be the rule. Having intentionally lacerated the placenta to some extent, with the result of but covering his fingers with blood, he ruptured the membranes, when only some blood-streaked liquor amnii escaped. Within three hours the labor terminated naturally. The placenta was soon expelled, but the uterus still felt like a large, doughy mass; but soon after the expulsion of about a pint of blood, firm contraction of the uterus resulted, and the case progressed favorably. This is one of the many cases which militate against Simpson's theory of hemorrhage in placenta prævia, and may also add some additional force to the objections against meddlesome midwifery.

Salicylic Acid in Typhoid Fever.

M. Vulpian, according to the *British Medical Journal*, has had great success with the internal use of salicylic acid in typhoid fever. He gives as much as a drachm and a half a day, in doses of four to five grains every half hour. He does not claim that it shortens the duration or lessens the mortality of the disease, but that it reduces the temperature. Of all patients treated, those who were given the acid improved most rapidly. By interrupting the treatment, M. Vulpian ascertained that the salicylic acid was really the cause of the lowering of temperature.

Bismuth in Dyspepsia of Children.

In *The Practitioner*, Dr. E. W. Dunbar, of Zurich, says that, for loss of appetite, in children, with pain after eating, nausea and depression, if accompanied by a tongue either clean or slightly coated, but showing redness and enlargement of the papillæ fungiformes, bismuth is very good. He gives it either in the form of subnitrate, in doses of one-half grain up to two, three and five grains, or the solution of the oxide in ammonia and citric acid, in doses of from two minims under one year to three, five, ten, fifteen and twenty minims, up to twelve years of age; the dose to be repeated twice, or four times a day, according to the severity of the symptoms. Bismuth is quite ineffectual in the dyspepsia of children, when the tongue is smooth, clean, and shows no enlargement or redness of the papillæ fungiformes.

Ferruginous Livers.

The interesting occurrence of an excessive quantity of iron in the livers of anæmic patients has been noted in Germany. Stahel and Lindenlang each describe a case. The *Lancet* says that Marchand has lately described the liver of a phthisical patient, aged sixty years, which presented an unusual brownish-red color, associated with evident cirrhosis. The microscope showed an infiltration of the hepatic cells and of the interstitial connective tissue by pigmentary corpuscles, which gave the characteristic test for iron with yellow ferrocyanide. A chemical analysis showed that the ashes contained not less than 30 per cent. of iron. It has been supposed that the excess of iron is the result of an abnormal destruction of red blood-corpuscles in the organ, but it is open to question whether it is more than the result of the free administration of iron by the mouth.

Treatment for Gout.

Dr. N. S. Davis, of Chicago, recommends forty drops of an equal mixture of the acetated tincture of opium and wine of colchicum seeds, to control acute paroxysms of gout. This dose may be repeated in an hour, if necessary. Oftentimes one or two doses will abort what threatens to be a very severe attack. When the paroxysm is under control the same remedies may be continued in smaller doses, three or four times daily, if any gout remains. We have used this remedy, and can add our endorsement to this distinguished recommendation.

To Prevent Necessity for Inducing Abortion.

The *Obstetric Gazette*, quoting from *Deutsche Med. Zeit.*, says that Depaul recommends in all such cases of contracted pelvis which indicate the necessity for inducing premature labor, that an attempt be made to lessen the size of the

child, by administering iodide of potassium to the woman.

He claims that this treatment was successful in a case of his, in which the conjugate of the true pelvis was from 7½ to 7¾ ctm. The previous three labors, in which she had no treatment, were very tedious and exhausting, while in this one labor came on at term, spontaneous and easy, the child living.

Correspondence.

Solution Ferrous Malate.

Ed. Med. and Surg. Reporter:—

Much attention has been given, of late, in many medical journals, to the use of the different preparations of iron. In your last week's issue I noticed the advertisement of the Solution Ferrous Malate. Having used this valuable chalybeate quite extensively in my practice, I have felt a desire to add my mite of testimony in the use of this remedy, for what it is worth. I commenced the use of Solution Ferrous Malate (as manufactured by the American Pharmaceutical Manufacturing Company) in my practice in April, this year, the first bottle having been sent to me by the manufacturing chemist, to give it a trial. I determined to test its virtues, and was so much pleased with the result that it has been adopted in my practice, and I have since the above stated time prescribed some 30 pounds. No objections to it, in any manner, have been made by any patients to whom I have prescribed it, and I shall continue to do so, believing it to be one of the most valuable and beautiful preparations of iron to which medical men have access in these days of intelligent and refined pharmacy. It has the following advantages, which increases its value to physicians: it exerts the therapeutic influence of iron without creating nausea, constipation, headache, or any of the unpleasant effects so often resulting from the use of the ordinary forms of iron. It is a proto-compound, very palatable, and readily assimilated. It forms clear solutions with compounds containing tannin, such as the gentian and cinchona preparations, properties which cannot be claimed for any ferruginous preparation of the Pharmacopœia.

G. T. Fox, M.D.

Bath, Pa.

News and Miscellany.

American Academy of Medicine.

The American Academy of Medicine met in this city, October 26th and 27th. The annual address was read by the President, Professor Traill Green, A.M., M.D., LL.D., of Easton, Pa. He referred to the organization of the Academy in this city, six years ago. He said one of the greatest obstacles to the improvement of medical education in this country is the deficiency of sufficient preliminary education in those who enter the profession. It is well known that but a very small proportion have had such previous training as is absolutely necessary in order to begin with advantage the study of a science. In 1876 the Medical School of Harvard was the only school in the country which required a preliminary examination of intending medical students. Now there are thirteen colleges which require the diplomas of a literary institution as a preliminary examination.

The President, in his address, also offered a number of practical suggestions.

The nominating Committee presented a report, which was adopted, and the following officers were elected to serve the ensuing year: President, Dr. Henry O. Marcy, Massachusetts; Vice-Presidents, Drs. George M. Beard, New York; William Elmer, Bridgeton, New Jersey; Cornelius R. Agnew, New York; Thomas M. Drysdale, Philadelphia; Secretary and Treasurer, Dr. R. J. Dunglison, Philadelphia; Assistant Secretary, Dr. Charles McIntire, Jr., Easton, Pa.

Drs. James M. Barton and Thomas B. Reed, of Philadelphia, were elected Fellows of the Academy.

On motion of Dr. Steiner, of Frederick, Md., it was agreed that at future meetings a collation shall be served after the delivery of the annual address.

Drs. Henry Frazer Campbell, of Georgia, and Austin Flint, Sr., of New York, were elected to honorary membership. A paper prepared by Dr. Nathan Allen, of Lowell, Mass., on the "Influence of Medical Men," was then read. It stated that at no former period in the history of medicine have the causes of disease been so carefully scrutinized. Never was there a time when the natural laws of disease could be studied to so good advantage—the principal cause and real nature of every distinct disease, and to learn that the whole mystery concerning disease arises mainly from ignorance. The profession has been inclined in the past to use altogether too much medicine, both in quantity and variety, which has produced serious evils. Drugs can never mend broken limbs, neither can they restore the system to a perfectly sound and healthy state when its inherent laws have been repeatedly violated Medical practice can never be reduced to a true system of test or science until the causes and laws of diseased action are better understood. Formerly *cure* was the supreme if not the leading object of the physician, but the time is fast approaching when *prevention* will be the watchword. No one question is coming before the public of such vital importance and magnitude as the prevention of disease, under the head of sanitary science. Its principles extend to the school, to the family, to the State, and to the Church.

Dr. Dunglison, from the Committee on Laws Relating to the Practice of Medicine in the United States, presented a supplemental report, which was referred to the Council, and the Committee continued.

Dr. Benjamin Lee, of Pennsylvania, said, this State, he was sorry to say, was one of the last to take steps toward the establishment of a State Board of Health.

Dr. Robert Lowry Sibbet, of Carlisle, Pa.,

said that this State was the home of quackery, and the city of Philadelphia had done a great deal to disgrace them. Over 6000 physicians have registered, 838 without diplomas. He then read a supplement to the Registration Act, to be passed by the Legislature in case of the establishment of a State Board of Health. It gives the Board of Health the power of receiving the registration of all practitioners of medicine and surgery.

Dr. Cornelius R. Agnew, of New York, said there was some discouragement in his State with regard to laws for the prevention of irregular practice. He had understood that, in consequence of the Registration laws of Illinois, about 2000 irregular practitioners have been driven out of that State.

Professor S. D. Gross, of this city, said he took a deep interest in this association, and was convinced the trees now planting by them would bear good fruit.

Dr. Charles McIntire, Jr., of Easton, Pa., read a paper on "The Academy and the Profession." It stated that in the Cumberland, Dauphin and Northampton counties, Pa., Medical Societies, and in the Medical Societies of Cumberland, Hunterdon, Monmouth, Salem, Warren and Atlantic counties, New Jersey, there were 222 members. Of this number, 28, or 12.6 per cent., were A. B.'s; 16, or 7.2 per cent., took parts of courses; and 178, or 80.2 per cent., had no college training. In 58 universities and colleges in the United States since 1820, there have been 38,054 alumni. Of this number, 3577, or 9.2 per cent., were graduates in medicine. The whole number of schools reported in 1879 was as follows:—Medicine, 68; Theology, 133; Law, 49. In 1880, Medicine, 72; Theology, 142; Law, 48. Number reporting no students at all: In 1879, Medicine, 2; Theology, 10; Law, 6. In 1880, Medicine, 5; Theology, 9; Law, 4. Actual number on which to base statistics: In 1879, Medicine, 66; Theology, 123; Law, 43. In 1880, Medicine, 67; Theology, 133; Law, 44. Number making no report of degrees in Arts and Science: In 1879, Medicine, 39; Theology, 53; Law, 19. In 1880, Medicine, 37; Theology, 68; Law, 18. Percentage of whole: In 1879, Medicine, 59.1; Theology, 43.1; Law, 44.2. In 1880, Medicine, 55.2; Theology, 51.1; Law, 41.0. Number of students reported by these schools: In 1879, Medicine, 5614; Theology, 2092; Law, 1218. In 1880, Medicine, 5279; Theology, 2537; Law, 768. Percentage of whole: In 1879, Medicine, 60.9; Theology, 48.0; Law, 40.3: In 1880, Medicine, 53.6; Theology, 49.9; Law, 24.5. Percentage of students in the schools reporting degrees in arts and sciences who have such degrees: In 1879, Medicine, 20.0; Theology, 59.0; Law, 43.0. In 1880, Medicine, 16.9; Theology, 52.6; Law, 32.0.

Only a small percentage of the estimated 83,000 practitioners of medicine in the United States are eligible for membership to the Academy, and only a small proportion of the graduates in arts study medicine. The need of a thorough preparation for medical men is certainly the cause for the Academy's existence, and the methods which will best cause this need to be felt are the methods which should claim the attention of the Academy.

If every practitioner in the country, or even a large majority, possessed the qualifications for fellowship, there would have been no reason for organizing the Academy.

After the induction into office of the President-elect, Dr. Henry O. Marcy, and the appointment of Dr. Benjamin Lee, of Philadelphia, and Dr. L. D. Bulkley, of New York, to fill vacancies in his council, the Academy adjourned to meet in the city of New York in September, 1883.

Dr. Klein on Vaccin Charbonneux.

The *Lancet* says that Dr. Klein has arrived at conclusions (based upon comparatively few experiments) adverse to the general adoption in England of Pasteur's proposal to inoculate cattle with anthrax, as a prophylactic. After giving particulars as to the way in which M. Pasteur's agent sells the "vaccin charbonneux," the directions for the use of which say that the "premier vaccin" is to be used first, and after a lapse of from twelve to fifteen days the "deuxième vaccin" is used in the same manner, Dr. Klein goes on to relate his experience with it. "I have obtained through two independent sources two lots of this vaccin charbonneux (premier and deuxième), and have tested them by experiments. The results of these experiments enable me to say—(*a*) animals inoculated with this 'vaccin' (premier and deuxième) are not made immune against fatal anthrax; and (*b*) both the first and second vaccin may produce fatal anthrax. The following facts prove these propositions:—

"*Experiments with Lot A.*—Inoculated with 'premier vaccin,' two sheep, two guinea pigs and two mice; no change in any animal. Inoculated with 'deuxième vaccin,' the two above sheep and the two above guinea pigs. One of these sheep showed rise of temperature and falling off in food for the first two days after this second inoculation, but was all right again after three days. The two guinea-pigs were dead of typical anthrax within forty-eight hours. The above mice were inoculated with the blood of one of these guinea-pigs. Both mice were dead of typical anthrax within forty-eight hours. The two sheep having been inoculated with the premier and deuxième vaccin, ought to have been immune against fatal anthrax. Now see what happened: according to M. Pasteur, the *Bacillus anthracis* of blood of an animal dead of anthrax, when cultivated at 42°-43° C. for twelve days, loses all virulence and becomes thereby converted into 'vaccin.' I had grown the *Bacillus anthracis* of blood of a guinea-pig dead of anthrax at a temperature of 42°-43° C. for *twenty-one* days, and with this culture I inoculated the above two sheep. The result was that both animals were dead of typical anthrax within forty-eight hours.

"*Experiments with Lot B.*—Inoculated with 'premier vaccin' four guinea-pigs and six mice. Within forty-eight hours three of the guinea-pigs and three of the mice were dead of typical anthrax. My method of using the fluids for in-

oculation absolutely precludes any accidental contamination, and hence these must be accepted as perfectly reliable. This country is comparatively free from anthrax, and therefore the introduction and use of this so-called 'vaccin charbonneux' seems to me most dangerous, and capable of producing incalculable mischief."

Ophthalmological Statistics in the United States.

The following interesting statistics are given by Dr. W. S. Little, in a recent article: The statistics of ophthalmic hospitals and ophthalmic work in general hospitals in the leading cities of the United States afford the following: Of 107,383 eye cases, 19,037 required surgical procedures, of which 862 were enucleation of the eye for some of the many forms of objective traumatism; principally on account of the dread of or presence of sympathetic irritation or sympathetic ophthalmia of the other eye; some for intraocular conditions, and a few for cosmetic purposes.

Thus 17.7 per cent. of ophthalmic work is operative, and 4.5 per cent. is enucleation of the eyeball. This percentage for the operation of removal of the eyeball should be higher than the statistics derived from the public clinics, as this class of cases are more apt to seek private advice.

The importation of artificial eyes is about ten thousand annually, and recently the manufacturing of them has become a home industry.

Cholera Rumors.

Some severe form of intestinal disorder has been recently raging in Chiapas and Tabasco. It is asserted to be Asiatic cholera. Cases alleged to be of the same character have been of late occurring at Matamoras. In fact, from various parts of Mexico and Central America there are disquieting rumors of the presence of this dreaded pestilence.

The Question of Population.

The following, from the *Med. Times and Gaz.*, is interesting: In general, in Europe, the increase of Catholics, Protestants and Jews, compared with each other, is as one, two, three; but in France and Austria the increase of Jews is four and seven times greater than that of Catholics. This does not depend upon the greater number of births among the Jews, which is usually inferior to that of Catholics and Protestants, but the number of illegitimate births is very much less among the Jews than among the other inhabitants; and as the mortality of infants is especially noteworthy in the category of illegitimate children, the result is that, although the Jews have fewer infants than the Catholics and Protestants, they preserve a greater number of them. Another curious fact is the sex of the children. In the European population in general, this is about one hundred and five male to one hundred female births; but in most countries where Jews abound, as Russia, Prussia, Austria and Hungary, the proportion of male births rises to one hundred and ten, one hundred and twenty, or even to one hundred and thirty, instead of one hundred and five; and M. Lagneau attributes this great predominance of male births among the Jews to the fact of the early age at which they marry.

The Yellow Fever.

Nearly 2000 cases of yellow fever at Pensacola is a frightful showing. Fortunately the type does not seem excessively malignant. Meantime the local Board of Health there have fallen out, both with the city government and the U. S. Marine Hospital Service.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

ON ALBUMINURIA.

BY M. DREYFUS-BRISAC,

Of the Paris Faculty.

Gentlemen:—The preponderating place occupied by renal pathology in the scientific discussions and memoirs of the present day explains the incontestable predilection of contemporary scientists for all questions bearing on the urinary functions, whether in a normal or pathological condition.

Hence the numerous researches into the mechanism of urinary excretion in the normal condition, and into the pathogenesis of the diverse modifications it undergoes when disease is present.

Albuminuria is not only the dominating symptom of renal semeiology; it is also a very important symptom in acute general diseases, whether infectious or not. To determine, then, absolutely the pathogenesis of the disease would be of very great service, from a clinical and pathological point of view. This has no doubt been well understood by the numerous observers who have to this end experimented in many different ways. The question is yet far from being elucidated, but many erroneous opinions have been exploded, and we have at least arrived at certain elements for the definitive solution of the problem.

It will then be my duty to first lay before you what is at present known on the subject, and this is rendered comparatively easy by the remarkable memoir of M. Charcot (Leçons sur les conditions pathogeniques de l' albuminurie, Paris, 1881).

To commence with, is the expression "pathogenesis of albuminuria," absolutely correct at the present time, when there is a tendency to consider the transudation of albumen through the renal epithelium as not always denoting a pathological condition of these organs?

Can it be considered that this phenomenon may be, in some cases, a simple anomaly compatible with apparent good health, or may even exist, in a very slight degree, as a physiological fact? Such is the question which, first brought forward in vague terms by Vogel, has since led to numerous researches in England and Germany. Among these last is an important memoir by Senator, which has just appeared (l' albuminurie á l' etat de Santé ou de maladie. Berlin, 1882).

Although unacquainted with this work, except through the interesting analysis of it given by M. Lépine (*Revue de Médecine*, No. 6, 1882), and the compte-rendu published in the *Centralblatt* (June 24th, 1882), we will yet be able to indicate the principal conclusions at which he arrives. As observed by M. Lépine, it must be admitted henceforth, that a number of individuals, particularly young and feeble subjects, may have for months, and even for years, a certain portion of albumen in the urine without presenting otherwise any appreciable alteration of the general health. "This opinion, the knowledge of which is important to the practicing physician, is founded on a sufficient number of facts to perfectly establish its exactitude.

Nevertheless, the many observations of latent

albuminuria brought forward, since attention has been called to the subject, are far from being always conclusive.

In the first place, all cases must be eliminated where any renal affection has existed anteriorly or where the patient has had any of the infectious diseases, which, like scarlatina, has a predilection toward the kidneys.

On the other hand, the denomination latent albuminuria is not applicable to cases occurring, particularly in children, who, without presenting any well defined morbid type, are none the less in poor health or in a state of marked anæmia. Of such a nature are the observations published by Gull, Dukes and Moxon.

The conclusion to be drawn from these facts is that albuminuria may be present, under certain illy-defined pathological conditions, without any other morbid sign of renal origin and without any appreciable lesion of the organ itself.

In a second category may be placed the numerous observations of individuals absolutely healthy, who present albumen in the urine after great fatigues or muscular exertion (Marcacci), or violent emotions (Fürbringer). In such cases, which approach very closely to pathological conditions, the transudation of albumen may be attributed to rapid modifications in the constitution of the blood, or to a passing perturbation of the renal circulation, of nervous origin (Bamberger, *Wien, Med. Woch.* Nos. 6 and 7).

It would seem at first, that this hypothesis of a vaso-motor trouble, to explain transitory albuminuria, receives support from the well-known fact that albuminuria sometimes occurs just after a convulsive attack, particularly in epilepsy.

But does this post-epileptic albuminuria exist in reality?

It appears doubtful, after reading the memoir of Kleugden. According to this author albumen is often sought for, simply because there has been a convulsive attack, but it may have existed in the urine long before the attacks called attention to the renal function. He affirms that albumen can be found not only in the urine of epileptic patients, but also in appreciable quantities in the urine of many healthy individuals, if it be sufficiently concentrated; he affirms that he has found appreciable quantities of albumen in the urine of more than half the healthy nurses in the institution with which he is connected.

Kleugden thence concludes that any urine of high density may present traces of albumen; albuminuria would be then almost a physiological fact. Senator seems to incline toward this view, but without formulating any decided opinion.

This point reserved, Senator establishes the fact that well-characterized albuminuria, where the proportion of albumen is as high as one per thousand, is in no way incompatible with the existence of good health. It is not either a permanent symptom, for in almost all the individuals under observation, this form of latent albuminuria presents a periodic or rather an intermittent type.

Appearing at certain moments of the day, either in the morning, or after meals, and then disappearing spontaneously. Thus it continues, without any alteration of the general health, and therapeutic interference, milk diet, etc., do not bring the urine to the normal condition.

What is the mechanism of latent albuminuria? A dyscrasic state of the blood cannot be the cause, for the individual enjoys good health; for the same reason the hypothesis of an actual renal lesion cannot be sustained.

To attribute it to very marked slowing-up of the circulation (Bamberger) or to an original abnormal permeability of the glomerular membrane (Leube, Fürbringer), is simply seeking to mask our ignorance by a hypothesis which is not susceptible of proof. Perhaps, some day, in studying more minutely the conditions under which this latent albuminuria is produced, we may arrive at indications of great service for the elucidation of the pathogenesis of true pathological albuminuria.

Three theories are, as you are aware, put forward to explain the passage of albumen in the urine; each one of the theories has very able defenders, and undoubtedly possesses some elements of truth.

Albuminuria is always the symptom of a more or less pronounced lesion of the epithelium of the renal canaliculi; this is the anatomical theory. It is due to derangement of the renal circulation—the mechanical theory; and finally it is the direct consequence of an alteration in the blood itself, which is the dyscrasic theory.

The first, or anatomical theory, adopted by M. Lecorché in his classic treatise, can no longer be defended in the absolute form he gave to it. Without speaking of latent albuminuria, "how can be explained by this theory those cases of transitory, yet morbid, albuminuria, which do not accord well with the existence of a material persistent lesion?" (Charcot.)

Even where epithelial lesions exist, it is by no means proven that they induce albuminuria. Physiological experimentation has, in effect,

shown that the tubuli recti, and even the tubuli contorti, have a very secondary part in the transudation of albuminoid matters, and that these are exclusively filtered through the glomeruli.

If artificial albuminuria is produced by temporary ligature of the renal artery, or certain forms of nephritis be studied at their debut (Ribbert, Cornil), it will always be found that the first deposit of the albuminous matters takes place in the capsule of the glomerule. The organic lesion cannot then account for the albuminuria, when it is limited to the tubuli recti and contorti, as it is in catarrhal nephritis. In nephritis affecting the glomerule, this theory would seem to have more foundation in fact.

It can be easily understood that an irritative condition of the glomerular membrane, produced by a substance like cantharides, or by a parasitic agent, as in scarlatina, may give rise to modifications of the structure and functions of the glomerular apparatus, whence the free passage of the albumen of the blood into the urine. But, as we will soon see, the renal traumatism and the lesions which then result, constitute but the second act of the morbid process; the first consisting in an alteration of the albuminoid elements of the blood, which act as foreign bodies in irritating the epithelial lining of the glomerule.

Thence the domain of the anatomical theory becomes very much restricted, the more so that in the infectious diseases, as we have elsewhere shown (*Gaz. Hebd.* 1882), the albuminuria is often due to the dyscrasic state of the blood.

The mechanical theory reposes on more solid foundations, particularly if modified by the new indications furnished by recent physiological data.

It would seem, as M. Charcot has established, that it was necessary to abandon the old opinion that albuminuria is due to an augmentation of pressure in the circulation of the glomerule. The classic experiments of Goll and Stockvis show that an excess of pressure in the renal vessels of the kidney does not suffice to produce albuminuria; and those of Overbeck and Rüneberg show that a fall in the pressure is a more favorable condition for the transudation of albumen.

But another factor of preponderating importance requires consideration; this is the slowing up of the course of the blood.

Posner and Litten, as also Bamberger, insist on this point.

Here are, however, the very explicit conclusions of M. Charcot on the subject:—

"In all cases where troubles of the general or local renal circulation give rise to albuminuria, it is not the augmentation or diminution of pressure in the intra-glomerular circulation which must be incriminated; it is the slowing-up of the blood current, and on this account the prolonged sojourn of blood containing very little oxygen in the renal capillaries."

Thus in conjunction with a purely mechanical perturbation of the circulation, another element is brought into play, the anoxæmia of the epithelial cells of the glomerule. Under this form the mechanical theory accounts for the albuminuria occurring in diverse morbid conditions, as in cardiac disease, the cyanotic state of cholera, and even in certain febrile states. But as regards true Bright's disease, is not the dyscrasic theory more satisfactory? This is what we will attempt to elucidate, relying principally on the works of Semmola.

The dyscrasic theory had for partisans such eminent clinicians as Bright, and Graves, and Gubler; unfortunately their conceptions, of exclusively theoretical origin, reposed on no direct proof. Thus no well-marked fact has justified the supposition of Gubler, "that the excess of albumen in the blood, relatively to the proportion of the globules and to the loss of the body in proteic matters, is the ordinary cause which determines albuminuria.

This doctrine was abandoned for that which invokes a modification, not quantitative, but qualitative, in the albuminoid constituents of the blood; this is the theory of Semmola which M. Jaccoud has formulated in these terms in his thesis of 1860:—

"Albuminuria recognizes as cause a deviation from the normal type of the processes of nutrition. This deviation consists in a temporary or durable perturbation in the phenomena of assimilation or disassimilation of albuminoid matters."

The albumen, altered and modified in its chemical or molecular composition, is a foreign body in the organism, and not being assimilable will be eliminated.

Evidently, in order that this theory, particularly applicable to Bright's disease, should be acceptable, it was necessary to prove that these alterations of the albumen of the blood really existed. It is on this question that discussion has been most bitter. Until recently it seemed to turn in favor of the adversaries of Semmola's doctrine, through the researches of Stockvis. This eminent observer affirmed that in albuminuric patients the albumen of the blood is not modified, from a chemical point of view; and

that, on the other hand, the coagulable principle of the urine does not differ from the normal serum of the blood.

But these conclusions have been proven partly false by numerous researches. The presence of abnormal albumen, differing from the ordinary albuminoid principles of the blood, has been frequently reported. On the other hand, M. Lépine has shown that the albumen contained in the urine has special characters at the period of digestion (more rapid diffusion, more prompt peptonization). In the same way tend Prof. Bouchard's works (1°. De l'albuminurié dans la fièvre typhoids, 1881, p. 325; 2°. Des nephrites infectieuses, 1882, p. 21).

Finally, in recent memoirs, read before the Congrès d'Amsterdam, Semmola brought forward new facts to the support of the dyscrasic theory as regards Bright's disease. To demonstrate that this alteration of the albuminoid principles of the blood is not imaginary, he studies their degree of diffusibility in serum, and finds that it is only in Brightic patients that they can be more or less completely diffused, according to the gravity of the disease.

And as these altered albuminoid matters, improper for assimilation, should be rejected from the organism, he has sought for, and found, albumen in diverse secretions ordinarily non-albuminous—in the bile, the sweat, the saliva. Whence the conclusion, that in Bright's disease the albumen of the blood plays the part of an excrementitial substance, and, if it passes largely by the kidneys, it is because these are the excrementitial organs par excellence.

Then, according to this theory, Bright's disease should be thus interpreted: primordial alteration of the albuminoid matters of the blood, causing their elimination by the diverse excretory apparatus, particularly the kidneys; consecutive trouble of the function of the glomerule, and finally organic alterations of the renal parenchyma, which are the consequence and not the cause of the albuminuria.

It remains for me, as a conclusion of this brief study, to consider the part of each theory in the pathogenesis of albuminuria.

1st. The cases of albuminuria imputable to a primitive organic lesion of the renal parenchyma, or of the glomerular apparatus, are those where the blood contains an irritating principle, as cantharides, or an infectious micro-organism, and even in such cases there may have been a primordial alteration of the blood globules.

2d. If troubles of the circulation produce albuminuria, it is by a different mechanism from that admitted up to the present; the transudation of the coagulable principle is due to the slowing up of the course of the blood, with anoxæmia of the glomerular cells.

3d. Bright's disease is but the symptomatic expression of a chemico-molecular alteration of the albuminoid matters of the blood, of a dyscrasic state, in fact.

This "leucomuric diabetes," as Gubler termed it, should be considered in the same category as saccharine diabetes, in the class of diseases to-day so comprehensive, caused by a deviation from the normal nutritive processes.

Communications.

HEPATIC COLIC (SO CALLED) FOLLOWED BY THE PASSAGE OF A LARGE BILIARY CALCULUS.

BY H. C. YARROW, M.D.,
University of Pennsylvania.

Read before the Medical Society of the District of Columbia.

Mr. President and Gentlemen:—I desire to exhibit this evening a large biliary calculus, recently passed by a patient of mine, and with your permission, will read my notes of the case, alluding to a few reports of similarly large gall stones.

Was called to see Mrs. X, a widow, aged 51, February 25th, 1881, at 5 o'clock P.M., and found her suffering from intense paroxysms of pain over and in the right hypochondriac region, which she was inclined to consider were due to an attack of sub acute gastritis, she having suffered from this disease for a number of years. The pain seemed to commence a little below the right nipple and extended to the umbilical region, the duration of the attack being about five minutes, with an interval of perhaps ten minutes. Her temperature was normal, the pulse slightly accelerated only, tongue coated with a heavy yellowish fur; the conjunctiva was yellow, and there was general icterus of the face; she had also some nausea, although she did not vomit while I was present. The patient's history of the case is as follows: About two weeks previous to my visit she had a general feeling of malaise; her head was dizzy and her bowels constipated; she took some domestic remedies, but continued in pretty much the same condition until within forty-eight hours of my visit, when she vomited freely. During this period of two weeks she had no cramps or colicky pains whatever, but on the morning of

Saturday, the 25th of February, at 7 o'clock, the first pains commenced, which increased in intensity up to the time I saw her, at 5 P.M., but which did not reach their acme until 7 P.M. After watching by the bedside for a few minutes and hearing the patient describe the pains as of a tearing or lacerating character, I made up my mind that a biliary calculus was passing through the ductus communis choledochus and having little faith in the internal administration of the various remedies which have been proposed for the purpose of dissolving engaged calculi, I simply gave her morphia in sufficient quantity to narcotize, trusting that time would relieve her sufferings. In addition, she was rubbed downward from the point where the pain commenced to the point where it ended. As I have remarked, the acme of pain was reached at 7 P.M., after which time she vomited large quantities of bile, and gradually became easier, so that when I again saw her, at 10.30 P.M., she was quite comfortable. She was ordered a dose of cathartic medicine for the morning, and the family requested to be on the watch for anything suspicious that might appear in the stools.

The calculus was passed Monday morning, February 27th, at 3 A.M., and within 48 hours, with the exception of a little intestinal soreness, she seemed quite well.

Apart from the large size of the calculus, the most interesting fact of the case is the apparently short time that was required for the passage of the stone from the gall-bladder, through the cystic and common duct into the duodenum, for, if we count the time, we find that the process required from, say 7 A.M. of Saturday until 7 P.M. of the same day. Another feature of interest is the passage of the stone, large as it is, through a tube so small as the common duct; although a number of cases have been reported of the passage of larger stones, in most of the instances communication has been established between the gall-bladder and intestine by a process of fistulous ulceration. This procedure, however, takes time, and I do not think it happened in my case. I have looked over the literature of biliary calculi, and will relate briefly a few histories of interesting cases of very large stones. To my friend Dr. Lamb I am indebted for the history of the largest biliary calculus at present in the Army Medical Museum, and he has also kindly furnished me with a great number of references to cases in which the duct has been enormously enlarged; these would be given did space permit.

"Two very large biliary calculi, passed by stool after symptoms of obstruction of the bowels, by a middle-aged man; one of them an inch long by an inch in diameter, and weight 182 grains; the other, $1\frac{1}{8}$ inch in diameter, weight 154 grains; each of these calculi is a truncated segment of a cylinder, the terminal facets passing obliquely to the axis, giving them the form of blunt wedges. They do not fit together, so that there must have been at least three others in the gall-bladder at the same time with these. They are composed wholly of cholesterine, with a little pigment. Subsequent to the passage of these calculi, the patient had symptoms of peritonitis. The patient was rather a fat man, about 50 years of age, with no previous history of hepatic colic. When seen by Dr. Toner, in the latter part of August, 1874, he was suffering from marked symptoms of obstruction of the bowels. When, at length, the passage was obtained, the two gall stones above described came away with it. Another, of considerable size, was passed subsequently, but not preserved. The patient is not aware of having passed any others. After the obstruction of the bowels had been overcome, severe peritonitis set in, so that for several days the patient's life was despaired of; he, however, recovered, and by the middle of September was quite well again."

The specimen was contributed by Dr. J. M. Toner, of Washington, D. C.

Rapin, in *Bulletin de la Societé Médicale de la Suisse Romande*, 1874, viii, 446, speaks of a calculus passed by a lady, aged 35 years. Taken sick, suddenly on the 8th of October. On the 11th was much worse; up to 18th suffered frightfully, with bilious vomiting; no icterus. On the 18th, as Dr. Stroehlin palpated the right flank of the patient, there was a sudden cessation of pain. On the 20th purging occurred, and finally, a stone of an oval shape was passed; in the evening another was passed. The first stone weighed 17 grams, was 4 centimeters long, and its greatest width was 3 centimeters. The second was the size of a bean. It is thought by the author that the common duct had enlarged sufficiently to allow of the stone passing.

Leared, in the *Transactions* of the Pathol. Soc. of London, 1865, xvi, 159, speaks of a biliary calculus, shaped like an olive, $1\frac{1}{4}$ inches long and one inch in diameter, passed per anum, by a woman, after 30 hours of pain and suffering, with vomiting.

Dr. James S. Bailey, *Phila. Med. Times*, 1874, iv, p. 683, found in the gall-bladder of an old lady, after death, a gall stone weighing 294

grains. Patient 76 years of age. Considerable trouble experienced during life.

Dr. Benson, in *Dublin Med. Press*, 1851, xxv, 337, relates a case in which, after many severe symptoms in a patient, a male, 56 years old, which lasted nine months, a biliary calculus, the size and shape of a walnut, weighing over half an ounce avoirdupois, was voided per anum, 4½ inches in circumference, lesser size 3½ inches; thought to have passed through the duct. He, Dr. Benson, to prove the dilatation of the common duct, exhibited one that was as large as a dollar, taken from a patient of the late Mr. Todd.

A calculus is described by Dr. G. Collins, in the Boston *Medical and Surgical Journal*, 1858, lviii, 120, which was ten inches long, $1\frac{5}{16}$ inch wide, and weighed six drachms. Symptoms commenced, in female, aged 50, on February 7th, and on the 14th of March, 42 days afterwards, the calculus presented at the anus and was removed by the finger.

Dr. L. Condit, *New Jersey Medical Reporter*, Burlington, 1851-2, vii, 393, relates a case of calculus, 1¼ inch long, 3 inches in circumference, weighing ℥ ss and ℥ ss, which was passed from rectum after four days of severe illness, and which caused the death of patient. Post-mortem showed that a direct communication existed between the gall-bladder and the duodenum, the common duct being obliterated.

A number of other interesting examples might be given, but I do not desire to trespass too much on good nature. As to the treatment of biliary calculi, the subject is one that has been discussed for ages, and the text-books will furnish very much better advice than I can give.

The calculus which I now exhibit needs no detailed description; it is obviously a monolith, and weighs, or did weigh, the day of its passage, 143 grains and a quarter. It lost probably 10 or 15 grains in the washing it received before it came into my hands. It has not been examined to determine its composition, but it is probably composed, in great part, of cholesterin.

The wood-cut, from an actual size drawing, by my friend, Dr. McConnell, of the Army Medical Museum, offers a good representation of this large calculus.

—Fears are entertained that the cholera, now raging in the East, may be carried into Europe.

DISLOCATION OF THE SPINE—REDUCTION—DEATH AFTER TWELVE DAYS.

BY J. S. WIGHT, M.D.,

Professor of Operative and Clinical Surgery at the Long Island College Hospital.

Mr. M. S., 62 years of age, born in Ireland, Port Warden, on the morning of June 3, 1882, fell into the hold of a vessel, a distance of about fifteen feet, upon the edge of a bale of jute, striking the small of his back, and was conveyed to the Long Island College Hospital, near ten o'clock in the forenoon, where I saw him on his arrival, and made note of the following points: The shock was very great; there was complete paralysis of sensation and motion in the lower limbs; the pain in the back was severe; the last dorsal vertebra with all the lumbar vertebræ projected backward; the eleventh dorsal vertebra with the rest of the dorsal vertebræ projected forward; the antero-posterior displacement was about one inch. The diagnosis was dislocation of the spine between the eleventh and twelfth dorsal vertebræ, complicated with fracture, the cause being direct violence.

A consultation was held at two P.M., on the day of the injury, when it was decided to make an attempt to reduce the dislocated segments of the spines: Drs. Burge, Mason, Atkinson and Wight were present at the consultation. The time set for the operation was four P.M., two hours later: The patient had just vomited, and it was thought that he would be in good condition by that time.

The operation was performed at four o'clock: Prof. Ford, Drs. Burge, Atkinson, and Wight were present. I operated in the following manner: After the administration of ether, I requested Dr. Atkinson to reach over the patient from above and put a hand into each axilla; Prof. Ford and the surgical interne each took hold of a foot; Dr. Burge watched the pulse and respiration: I then put an ordinary pillow under the patient's back, so that the pillow was about equally under each segment of the dislocated spine, and put my right hand under the upper end of the lower segment, and then put my left hand on the sternum: Then Dr. Atkinson made careful upward extension, and Prof. Ford and the surgical interne made downward extension, and at the same time, I pressed upward with my right hand and downward with my left hand, when about two-thirds of the distance of displacement disappeared, giving slight crepitus; two or three similar attempts did not effect any change in the position and relation of the segments: I then directed Dr. Atkinson to

raise up the shoulders of the patient, making extension at the same time, and then lowering the shoulders, during which manipulations I again pressed upward with my right hand on the upper end of the lower segment of the spine and downward on the upper segment with my left hand on the spine, when the segments became so completely reduced to the position they were in before the injury, that it was not possible to detect any material displacements. The pillow was left under the back. The patient was in good condition when the influence of the ether passed away.

The following points of interest in this case may be noted:—

1. There was retention of urine from paralysis of the bladder, complicated with stricture of the urethra. I found it impossible to get a catheter into the bladder; I succeeded in introducing a whalebone guide through the stricture, and the next day I put a divulsor over the whalebone guide, into the bladder, and divulsed the stricture to the size of a number twelve sound; then I introduced a number eight catheter, and kept it in the bladder, directing the urine to be drawn off about every three or four hours.

2. In two or three days after the reduction of the dislocation, the patient could make slight motion of his lower limbs, he could perceptibly rotate the feet and legs. He would will to move his legs, and after some twenty-five or thirty seconds the rotation of the feet and legs could be seen. This slight return of voluntary motion lasted about seven or eight days, and then completely disappeared. The patient never had the least sensation in his lower limbs, all sensation so far appeared to be lost. Hence it would appear that the sensory tract of the spinal cord had been more damaged than the motor tract.

3. The bowels were moved from time to time by stimulating enemata, but were very constantly distended with gases, giving considerable annoyance. The quantity of urine varied from 32 to 52 ounces in the twenty-four hours. The divulsion and laceration of the tissues constituting the stricture did not appear to do any special harm. The temperature varied from normal to 102°. The pulse varied from 60 to 104 per minute.

4. While the friends of the patient were told that he could not recover, they were quite hopeful that all would be well, and one doctor told a special friend of the patient that he had treated such a case and recovery had taken place. Is not judgment as rare as human charity? The patient grew weaker and weaker, and died quietly, at half past five o'clock, P.M., June 15th, 1882. No bed-sores had formed. And I regret to say, that the friends did not permit a post-mortem examination.

DIPHTHERIA A CAUSE OF DEAFNESS; NOT ONLY IN SCHOOL CHILDREN, BUT ALSO IN ADULTS.

Abstract of Paper read before the American Medical Association, in 1882.

BY LAURENCE TURNBULL, M.D.,

Aural Surgeon, Jefferson Medical College Hospital, etc.

In this paper there is carefully detailed the influence of defective arrangement of water-closet and drainage, in which sewer-gas charged with diseased germs affected three persons with diphtheria and another with catarrhal pneumonia, and showing that pharyngeal catarrh increased the predisposition to diphtheria. The Doctor is of the opinion that it is very rarely, if ever, of spontaneous origin, but is propagated from secretions, etc., of person to person in the same atmosphere. He dwells upon the mortality, giving his own observations as well as those from the Florentine epidemic, and he considers that it is more fatal in children of syphilitic or scrofulous parents than in those of good health. The symptoms and course of the disease is then treated in a typical case, with the treatment both general and local. The sequela is given, showing the paralysis of the muscles of the soft palate and pharynx, with its extension into the Eustachian tubes and middle ear, followed by deafness, which was treated by local agents and galvanic currents with marked success. His method was the introduction of the intra-tympanic catheter into the Eustachian tubes by means of a platina wire tipped with a copper ball. He states that it is of great importance to watch carefully diphtheria in young children, as at about the termination of an attack the inflammation may pass into the external meatus, or by means of the throat, into the Eustachian tubes or mastoid cells. This diphtheritic inflammation is sometimes fatal, and often impairs the delicate arrangements of the middle ear, more especially in syphilitic or scrofulous children, and even in those of apparently good sound health, unless promptly treated. In his examination of school children, he finds a large number deaf from this cause; and in another paper dwells more at length on this important subject. The paper concludes with a report from Dr. Morris Longstreth, Microscopist of Jefferson Medical College Hospital, of a careful micro-

scopic examination of a portion of the diphtheritic membrane removed from the post-nasal and Eustachian tubes, which throws some light upon this obscure but yet very important subject creating so much interest at the present day.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINICAL LECTURE BY WILLIAM GOODELL, M.D.,

Professor of Clinical Gynecology in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

Fibroid Tumor of the Uterus.

Gentlemen:—Our first patient presents the following history: "She is 33 years old; has been married two and a half years and is sterile; she has always had dysmenorrhœa and leucorrhœa. Since marriage she has been worse, the menses coming on every two weeks and lasting four or five days. She has a radiating pain in the left iliac region, a hot pain in the back, and a dragging sensation in the pelvis." The hot pain in the back does not mean anything in particular. It probably comes from nervousness; but the bleeding does not. It means something else and of graver import. She is 33 years old and sterile; from this, I should say that she has not cancer of the womb, for it is so rare for a woman who has never borne a child to have cancer of the uterus, that you may practically exclude it in an off-hand diagnosis. Exceptions to this rule do occur, but, as I have said, they are exceedingly rare.

Where bleeding comes on every two weeks in a sterile woman, we should look for a tumor. Most probably we shall find a polypus or a fibroid tumor. A polypus usually causes intermenstrual dribbling of blood. This case proves to be one of fibroid tumor.

I shall now make an examination per vaginam. The cervix is very small, and I can barely find the os. I introduce the sound and it disappears up to the handle. It causes a slight serous, semi-purulent discharge, which is frequently seen in cases of fibroid tumor. By the by, I have not examined this woman *secundem artem*. Before passing the sound, I should have asked when she had last seen her monthlies. The woman may have been pregnant. Physicians are apt to blunder sometimes. A woman comes to the office not knowing that she is pregnant, or she knows it and wishes an examination for a special object, and unless the doctor is on his guard he may bring on a miscarriage.

The sound has gone posteriorly, and I feel the point of it to the right of the umbilicus and about an inch above it. The tumor probably occupies the right side of the womb, anteriorly. Removing the sound, I find that it gives a measurement of nine inches. This shows that we have a foreign body in the womb, and we know that it is a tumor. Practically, the only tumor of the womb is the fibroid tumor. Sarcoma sometimes occur, but they are very rare. As we have such a large measurement, the tumor must be located in the walls of the organ.

I now examine the abdomen, in order to determine the presence or absence of fluid. This sort of a tumor deceives the physician, by making him believe that it contains fluid. In the first place it is a soft tumor, a soft fibroid, or, as it is often called, a soft myoma; and in the second place, a thrill is conveyed to the finger by the subcutaneous fat. Women with fibroid tumors retain their fat, while with ovarian tumors they emaciate rapidly. This I believe to be a soft myoma.

In regard to the treatment: I wish that this woman was forty-three years old instead of thirty-three, for then we might hope for benefit from the change of life. We, however, must resort to drugs. A good remedy is the chloride of ammonium, in ten-grain doses after meals. I usually give it in a teaspoonful of cinnamon water, which is an oxytocic, and at the same time helps to disguise the taste of the drug. I give it after meals, because it is then less likely to cause disturbance of the digestion. Before each meal I order ergot. She must regulate the dose herself. I direct twenty drops to be taken in a wineglassful of water, and if this does not make her sick at the stomach, and does not cause pain in the uterus, I tell her to increase the dose to 25, to 30, up to 60 drops or more, until it gives her pain in the womb. I should much prefer, however, to have her in the hospital, where I would give her hypodermic injections of Bonjean's ergotin, or of sclerotic acid, giving of the former a syringeful, or of the latter half a grain. If the hypodermic needle is buried deeply in the abdominal walls, there is but little danger of abscesses.

What is the rationale of this treatment? But first let me tell you that there are three kinds of fibroid tumors; one variety is located inside of the womb, beneath the mucous membrane. These are called sub-mucous. A second is found in the walls of the uterus, the interstitial or mural; and a third on the surface of the womb beneath the peritoneum, sub-peritoneal or surface tumors. The uterus is really a muscle, and if the tumor is within its wall, it is surrounded by muscular tissue. Ergot causes a tonic contraction of the uterine muscles, and we have the blood vessels so pressed upon that the tumor is shut off from its blood supply and gradually atrophies. In some cases ergot produces the most remarkable results, while in others it entirely fails. The chloride of ammonium is a good alterative and absorbent, and is useful in all glandular enlargements. In its action it somewhat resembles mercury.

I shall have this woman report in two weeks, that we may note the progress of her case.

Abdominal Tumor, Probably Ovarian.

The next patient is 35 years of age; married and has had one child, which is now 14 years old. The labor was not a difficult one. Four years ago she noticed a fluttering in the left iliac region, which lasted for a year. That was a nervous feeling. These flutterings are sometimes very extraordinary. We used to have a patient who came to us year after year, stating

that she was pregnant, and that she felt the motions of the child. Nélaton, a French surgeon, tells the story of a lady who, after having consulted many physicians, came to him, stating that she had been pregnant for a long time, and that from the period it had lasted, she thought it must be a son. Nélaton asked her how many years it had lasted; she replied "twenty one years." "Well, madam," rejoined Nélaton, "the best thing you can do is to swallow a tutor for that boy."

After the fluttering had continued for a year, she noticed an enlargement in the left iliac region. This has gradually increased until the abdomen has reached the size of the eighth month of pregnancy. At times this tumor causes considerable pain. She has been steadily losing flesh. The tumor has been growing pretty rapidly.

Examining the abdomen by palpation I find a bosselated tumor. At some points the tumor is evidently solid, but at other places there seems to be fluid. I also feel a friction fremitus, as though the peritoneum had been roughened. By the vagina, I find that the womb moves when pressed by my finger. The sound passes three and a half inches. The womb can be easily moved by the sound, showing that this tumor is independent of the womb.

I shall give this lady ten grains of the bromide of potassium in the compound infusion of gentian three times a day, and have her report in two weeks.

Why do I give the bromide of potassium? In the first place, I have to give her something; and remember that you have to sometimes give medicine when there is no indication for it. Patients feel that they ought to be taking something. In the second place, she is nervous, and the bromide will make her more comfortable and help to prevent her from worrying about her condition. I give it, however, more for its moral effect.

My impression is that this is a tumor of the ovary, but as to its character, I am not prepared to say. I am afraid that it is malignant. It may be a partly fibroid and partly cystic tumor of the ovary. The womb is clearly not implicated, unless united to the tumor by a long band. If the tumor goes on increasing, I shall make an exploratory incision. This possibly might be a tumor of the omentum, but I do not think it is, because the symptoms began on one side. As the trouble was first noticed on the left side, it is probable that the left ovary is the one involved. It is humiliating to think that only half an inch of flesh prevents me from making a positive diagnosis.

Cancer of the Vagina.

This patient is 50 years of age, and has had eight children, the youngest of which is 13 years old. About one year after the last confinement she had a severe hemorrhage, lasting for three and a half weeks, and at each succeeding menstrual period she had menorrhagia, accompanied by severe pains in the head. For the past six years there has been a discharge of clots, the periods lasting for three days. Last spring she had a hemorrhage, with severe pain and the discharge of large clots. Since then there has been no hemorrhage, but a profuse watery discharge, offensive in character.

When a woman who has borne children and is over forty comes to me and says that the change of life has occurred, and that some time afterwards she began to bleed, I expect to find a cancer, and in nine cases out of ten I am correct. If a woman gives me this history, I inquire if bleeding is caused by coition, and she usually tells me that it is. This shows that there is something against which the male organ impinges. It may be a polypus, but usually it is a cancer. When a woman of about forty comes to you and states that the menses instead of diminishing have gone on increasing in amount, you may find a fibroid tumor, or a polypus, but often you will find a carcinoma.

As I expose the parts you see a tumor projecting from the vulva. It presents the appearances of a true malignant growth. It is by no means common for carcinoma to appear externally. This has, I think, commenced at the cervix, implicated the vagina, and grown externally.

In my remarks on the first case, I said that cancer was very rare in sterile women. Why is this? It is because the disease has its seat in a tear of the neck of the womb. The cervix is lacerated; this leaves a raw surface which, by constant irritation, degenerates into a cancer.

I intend to remove as much of this growth as possible. In so doing I shall use these curettes, which are serrated on the edges. I shall work rapidly, and thus diminish the loss of blood, but if troublesome hemorrhage does occur, I would not use Monsel's solution, for it forms hard plaster-of-Paris-like clots, and corrugates the tissues to such an extent that I should have to postpone the operation. I have here a bottle of ordinary vinegar, which is an excellent hæmostatic, and if necessary, I shall inject that.

The vagina is a bad place to have cancer, because the tissues between the vagina and rectum are so thin that it is impossible to thoroughly remove the diseased structures. This makes the third case of cancer of the vagina that I have seen within a week. Let me give the history of one of them. A lady, aged 43, living about thirty miles from the city, had for some time past lost so much at her monthly periods that she thought the change of life was coming on. Last Saturday, while having the bowels moved, a large quantity of fæces passed from the vagina. She became very much alarmed, and a physician was sent for, who pronounced it to be due to a carcinoma of the vagina. This was a terrible blow to the lady. She could not believe that she had a disease of that kind. They sent for me, and I was to have gone on Sunday, but owing to the wash-outs on the railroad, I could not go until Monday. When I entered the house the husband came to me and begged me to give them some hope, and told me not to express my opinion to his wife (I make it a rule never to do so, anyhow). I made the examination, and found that it was a cancer of the vagina, which had opened into the rectum, and that it was absolutely useless to perform any operation. A case entered my office day before yesterday, in which I found exactly the same thing.

I shall not use here, as I usually do in cancer of the cervix, the actual cautery, for it would be of no earthly use. This operation is not going to cure her; it will benefit her for a while, but the disease will soon return.

Gentlemen, you can never overlook a cancer, you may mistake something else for cancer, but you will never mistake a cancer for anything else. If it affects the cervix, you will find an excavated sore, filled with rough, friable granulations and with a sharp edge around it. This crater-like feeling is unmistakable. The growth is usually an epithelioma, but it is said that it sometimes begins as a scirrhus, and eventually becomes an epithelioma.

After the operation I shall treat this sore with iodoform in large quantities. This is a good remedy in cancer. I do not know that it ever cured a case, but it retards the return, makes the patient more comfortable, and prevents her neighbors in the ward from suffering from her presence.

There is not much bleeding, but I shall inject some vinegar. This syringe does not draw the liquid up very well, and I thought the nozzle had been split. It would then illustrate one cause of sterility in cases of laceration of the cervix. During coition, at the height of the orgasm, there is undoubtedly a suction action exerted by the womb, but if the cervix has been torn, it cannot draw up the semen that lies beyond the split. If I were treating this case outside of the hospital, I should tie a string around a sponge which had been dipped in vinegar and leave it in the vagina, to prevent any danger of hemorrhage.

She will have but little pain from the operation, and in my experience, malignant diseases of the pelvis are very free from pain; but to be on the safe side, I make it a rule to use suppositories of the aqueous extract of opium. I give these because, as she is now under the anæsthetic, I could not administer opium by the mouth, and we also, by the suppositories, bring the drug very near the part which we desire to affect; the nearer we get the more marked will be the effect. I prefer the aqueous extract to the other preparations of opium, because it is not so apt to cause sickness of the stomach.

When the discharge of pus begins, I shall give quinia, to prevent septicæmia, using 12 grains during the day. If the temperature should rise, enough will be given to cause buzzing of the ears. We shall use antiseptics and deodorant injections of permanganate of potassium, which is, I think, one of the best antiseptics. It has but one objection, and that is, it stains the clothing. On that account I sometimes use injections of carbolic acid.

WESTERN PENNSYLVANIA HOSPITAL.

SERVICE OF JAMES M'CANN, M.D.

Reported by T. M. T. McKennan, M.D., Surg. Resident.

Case 1. Fracture at Base of Skull.

John Sanders, age 23 years, a fireman on the railroad, was brought into the hospital July 29th, 1882. His injury was caused in the following way: He was upon the cab of the engine when about to pass under a coal tipple, and was struck on the back of the head and knocked upon the tender. Being immediately brought to the hospital, he was found to be in the following condition, to wit: He was in a state of semi-consciousness, with his knees drawn up. He lay quiet, but upon being spoken to sharply opened his eyes and responded. Pulse 92. Bleeding at the nose slightly, and profusely from the left ear. No mark of violence was found. Was given five grains of potass. bromid. every hour. The bleeding from the nose stopped in two hours, but that from the ear still continued. The blood from the ear was venous and rapidly becoming lighter in color, until, within six hours, it was of a light straw color.

The next day, July 30th, his condition had changed. He was very restless. Pulse at 56. The left pupil was dilated, while the right was normal. An ice cap was applied. Ten grains of calomel was administered and the following also ordered: Fifteen grains of potass. bromid. and twenty gtts. of fluid extract of ergot, every three hours.

The discharge from the ear is still very profuse and straw colored.

The next day, July 31st, his condition is about the same. Discharge from ear lessened and stopped August 1st, after continuing 72 hours. Ice cap still kept up. Bromide and ergot continued. Pulse 56. Bowels moved freely. He talks in an irrational manner. Is still restless. He remained very much in this condition for about two weeks, when he began to improve. His left eye had a peculiar cast, the pupil being dilated still. His mind is clearing up, although he is very much like a child, and remembers very little of his past life, but he is improving every day. Discharged August 19th, his mind improving slowly, and we have since heard that he has entirely regained all his mental faculties.

Case 2. Hydatid Cysts of Liver and Spleen.

Mrs. R., age 36 years, admitted July 31st, 1882. She is a German, and has only been in this country one year. Has been married six years, and has two children. The last only ten months old. Three years ago she noticed an enlargement of her abdomen, near the liver, and consulting a physician in Germany, was told she had a disease of the liver, but he did not state its nature. No inconvenience, however, resulted from it until six months ago, when it began to increase rapidly, and at the same time the left side commenced to enlarge. This is since the birth of her last child, which is ten months old.

Present Condition.—The woman is five feet in height, weighing 100 pounds. Hollow cheeks and complexion of a dusky color, resembling very much that of Addison's disease. Abdomen very much distended. On inspection, two prominences are noticed, one on right side, in right lumbar region, the other in left lumbar region, and is the most prominent.

Palpation.—Fluctuation is distinctly felt for several inches around the prominences indicated, but not over the entire abdomen nor in the umbilical region.

Percussion.—Dullness is found to extend all over the epigastric, hypochondriac and lumbar

regions, and all the umbilical except the lower part. The hypogastric region is tympanitic, as are also the inguinal regions.

Aug. 5th. The cysts were tapped to-day by means of the aspirator, and 12 ounces taken from the right side, while 72 ounces were taken from the left side.

Chemical examination of the fluid showed it to contain no albumen, but an abundance of chloride of sodium. Specific gravity, 1.004.

Microscopical Examination.—In two drops of the fluid quite a number of ecchinococci were found, which rendered the diagnosis of hydatid cyst conclusive.

She was ordered 15 gtt. of acid. muriat. dil. every four hours, also 15 gtt. olei terebinthinæ three times a day. She appeared much relieved by the tapping, and said she felt much lighter. She improved somewhat in the next two weeks, but at the end of that time again became worse. The cyst on the left side had again filled, and upon being tapped was found to contain almost pure pus. She rapidly grew worse, and upon the 27th of September, died. A post-mortem revealed the following: Adhesion of liver and spleen to abdominal wall around the places corresponding to the punctures made by the aspirator. Spleen and liver both enormously enlarged and converted almost wholly into cysts. Adhesion of left lobe of liver to spleen.

(1st) *Spleen.* Found to be 12 inches long, 9 inches wide and 6 inches deep, made up almost wholly of cysts, which were seven in number, and contained different colored liquids, some clear, others dark, while others were almost wholly pus. The cyst which was tapped was found to contain a large clot of blood.

(2d) *Liver.* These cysts contain different colored fluids, also a number of hydatid vesicles, or daughter cysts. Some of the fluid stained with bile. There are nine cysts on the right lobe and three on the left lobe.

(3d) *Kidneys.* Right normal. Left kidney contracted, and when opened found to be converted into one cyst, containing caseous matter. Heart and lungs normal.

Case 3. Intercondyloid Fracture of Femur; Laceration of Popliteal Artery.

Frank Matush, Hungarian, age 40. While drunk was struck by an engine, and his right leg was squeezed in some manner, although not run over.

Was brought to the hospital at 6 A.M., September 24th, and was found to be in the following condition. Pulse 80. Considerable swelling about right knee. The ligaments seemed to be torn, as the leg could be bent in any direction. Foot and leg cold. No pulsation felt in either tibial arteries.

A diagnosis of laceration of the popliteal artery was made, and the attending surgeon, Dr. McCann was notified. Upon his arrival a further diagnosis of intercondyloid fracture was made. Amputation at the middle third of the thigh was immediately performed. The femoral artery was twisted. The flaps sprinkled with powdered iodoform and united by silver sutures. When turned over to the incoming surgeon, on October 1st, he was doing very well.

Medical Societies.

COLLEGE OF PHYSICIANS, OF PHILADELPHIA.

Autopsy of a Case of Transposition of the Viscera.

BY H. AUGUSTUS WILSON, M.D.

Pathologist to the Presbyterian Hospital and Ophthalmic and Aural Surgeon to St. Mary's Hospital, Philadelphia.

[*Read October* 4, 1882.]

The comparatively rare occurrence of the phenomena an instance of which I am about to relate will be, I think, sufficient excuse for occupying the time of the College. I regret that I am not able to offer a more complete record of the case; but a careful dissection was impossible without taking an unwarranted risk of septic poisoning, as the abdominal cavity was filled with fetid pus.

Frank M., aged 21, died at the Presbyterian Hospital, of purulent peritonitis. I shall ignore in this paper the pathological conditions found at the post-mortem examination, inasmuch as they have no bearing upon the subject under consideration.

The patient had been aware since boyhood that his heart was misplaced, and upon one occasion a physician told him that that was the reason he was left-handed. He had never been very strong; but it does not appear that he ever had any serious affection the cause of which could be assigned to his misplaced viscera.

In 1878, when he first came to the hospital, Dr. James Markoe, under whose care he was, noticed that not only was his heart perceptible in the fifth interspace of the right side, but also by percussion ascertained that this organ occupied the same relative position upon the right side that it should upon the left. He found also that the liver and spleen were transposed, but no further changes seem to have been noticed.

At the time I made the post-mortem examination I found externally nothing to indicate the great changes in the positions of the internal organs, except that the right testicle was suspended at a lower level than the left. When I had opened the thorax and abdomen, and laid bare the organs contained therein, the appearance to me was as though I was looking at the body reflected in a mirror. It was like the photographer's negative.

The heart first attracted my attention, and was found to be normal in every respect, but occupying, as already noted, a position upon the right side. It looked as though it had been pushed over to its present position without changing materially its relations with other organs. The right side was the pulmonary side and the left the systemic side, and in this respect the organ performed its function in a normal manner. The aorta, starting from the left ventricle, followed a somewhat irregular course, crossing over the right bronchus and going from there to the right side of the vertebral column, along which it descended upon the right side. The branches given off from the arch of the aorta were the two coronary arteries, unchanged, the innominate going up

the left side of the neck and giving off the left common carotid and left subclavian, while coming from the right portion of the arch were the right common carotid and right subclavian.

The lungs were reversed. The right lung was found to be smaller, to allow space for the heart. It had two lobes.

The left lung corresponded in appearance to what is commonly the right lung, was shorter than its fellow, being pressed up by the liver, was broader, and had three lobes.

In the abdominal cavity the liver occupied the left hypochondriac and partly the epigastric regions, the large lobe to the left and the smaller ones to the right, the gall-bladder and everything else similarly changed.

The stomach and intestines were transposed. The stomach was partly in the right hypochondrium and partly in the epigastric region. The pylorus extended forward and downward toward the middle of the abdomen. The spleen was on the right side, and attached to the greater curvature of the stomach.

The cæcum was situated in the left iliac fossa, and the colon ascended on the left side and crossed from left to right side of the abdomen. From there it descended and terminated in the sigmoid flexure upon the right side.

As already stated, the man was naturally left-handed. Hyrtl was the first, I believe, to advance the theory that we are normally right-handed because of the more direct flow of blood to the brain upon the left side. And this theory would be substantiated if all cases where the heart and great vessels were transposed were left-handed; but such is not the case. A few years ago a theory was advanced that right-handedness depended upon natural selection. But the easiest explanation is, that from earliest infancy we are instructed to use the right hand always, in preference to the left. When a person with transposition of the viscera is left-handed, we may call it a coincidence. In any other view, it would be extremely difficult to account for the far larger number of persons whose organs are arranged normally and yet are left-handed. In the cases that are noted in the journals, I have not been able to find statistics enough to draw any inferences, for, when this condition is noted, right-handedness appears to be as frequently met with as left-handedness in cases where the viscera are transposed.

Peacock, in his monograph on malformations of the heart (T. Peacock, *Malformations of the Heart*, 2d edit. 1866), says that the most common of all the internal displacements is that in which the heart is placed upon the right side, in a position corresponding to that which it should occupy upon the left, and that this displacement s almost always associated with more or less complete transposition of other viscera. Occasionally the heart is transposed, while the other organs are unchanged (Sur l'Ectopie de l'appareil de la circulation et particulièrement sur celle du cœur.—*Rep. Gen. d'Anat. et de Phys. Pathol.*, t. ii, 1826, p. 1).

Among the earliest recorded cases are those of Servius and Schenkius, in Rome, in 1643 (Thomas Bartholinus, *Hist. Anat. Cent.*, ii, 29. Amstelodami, 1654), and one by Riolan, in 1652 (Allen Thompson, Glasgow *Med. Journ.*, vol. i, 1853, p. 220).

The first case recorded in which the malformation was noticed during life appears to be that described by Morand (Méry, *Memoirs of Academy of Paris for* 1866), in 1666. This case seems to have attracted considerable attention at the time, and was said to have suggested to Molière the transposition of the heart and liver which he puts into the mouth of Sganarelle in his play of *Mèdecin Malgré lui*, published about the time this case was reported.

In cases of more or less complete transposition, the arteries, if they do not retain their natural positions, may be displaced in almost all conceivable ways.

Dr. Gamage (*N. Eng. Journ. Med. and Surg.*, iv. 1815, p. 244) reported a case in which the aorta arose from the right ventricle and the pulmonary arteries from the left ventricle. Mr. Abernethy (*Philosophic, Trans.*, 1793, p. 59) saw a child, ten months old, where the portal veins terminated in the vena cava, the liver being supplied from an unusually large hepatic artery. Mr. Douglas Fox (London *Med. and Phys. Journ.*, vol. li, 1824, p. 474) reported the result of a post-mortem examination in a case where the heart was transposed, and the aorta, after crossing the right bronchus, passed behind the lower end of the trachea, over the vertebral column, and pursued its usual course from there down the left of the spine.

For a very complete account of a case similar to the one I now report, and for an exhaustive study of the histology of such malformations, I will refer to Dr. Allen Thompson's paper in the Glasgow *Medical Journal.*

As regards the practical application of this case, it would be well to bear such abnormality in mind as a possible condition in cases brought to a physician's notice in an unconscious condition. It will readily be seen that considerable difficulty might arise in forming a diagnosis. In surgical operations upon thorax or abdomen it would prove a serious complication, as, for instance, in colotomy, paracentesis abdominis, or pericardii.

Effects of Puerperal Secretions on the Organism.

The *Edinburg Medical Journal* says that Karewsky has made a number of careful inoculation experiments on this subject, with the following results:—

1. All lochia, normal as well as septic, are able to produce septicæmic and ichorhæmic disease in animals. 2. The virulence of the discharge increases with the duration of the puerperium, and during puerperal diseases. 3. When symptoms of septicæmia appeared a spheroidal fungus was found in the organs of all the affected animals. 4. Diseases produced in this way are communicable to healthy animals. The fungus derived undoubtedly from the adjacent air, finds in the genital tract an extremely favorable seat for further development. The inoculated cases differed from each other only in degree. The globular micrococcus found in all the cases is evidently the *materies morbi*, although, of course, it is not a specific "*micrococcus puerperalis.*"

EDITORIAL DEPARTMENT.

PERISCOPE.

A New Departure in the Treatment of Rheumatism and Gout.

In the *British Med. Jour.*, Dr. Alexander Harkin presents an article in which he first points out the unsatisfactory state of our knowledge concerning the etiology and therapeutics of these two diseases, and afterwards condemns the now recommended salicylate treatment, and then goes on to recommend an entirely new treatment of his own. He says:—

"My object is not so much to call attention to the epidemic of salicism, from which, apparently, the medical mind is at present suffering, as to propose a new and effective remedy for acute rheumatism, which, in my practice and in that of other professional friends, has afforded results as yet unequaled in the treatment of that disease."

The following case will give a good idea of his method of treatment:—

On October 24th, 1879, I visited sub-constable H., aged 30, married. He had a rigor on the 21st, followed by pain in the left knee and thigh, which were now red and swollen. On the 25th pain had extended to the right knee, both ankles and shoulders. On the 26th the left elbow was also affected; perspiration was acid and profuse; his urine scanty and loaded with urates. On the 27th his state was unchanged. I ordered an opiate at bedtime. He had been previously laid between blankets, and his joints enveloped in cotton-wool. On the 28th he was no better; he had not slept for a week. At 1 P.M. his temperature was 102°, pulse 108. No cardiac affection was perceptible. I then applied a blister, four inches by three, over the region of the heart, to be replaced with cotton-wool at the end of eight hours. On the 29th I found the patient completely relieved. His countenance was cheerful, his tongue clean, thirst diminished, perspiration gone, urine copious and clear, temperature 98°, pulse 90. He told me that he began to feel relief at 6 P.M., just five hours after the application of the blister; that soon afterwards he fell asleep for the first time for many days; and that, having had occasion to rise in the night, he walked unaided across the floor, and only remembered his pains after getting into bed. And thus, although on the previous day paralyzed in every joint, he was now able, without pain, to flex and extend them all, and to sit up in bed with ease. On looking at the joints, every trace of redness had departed, and the swelling was very much diminished, and they could be grasped firmly without pain. On the 29th and 30th he was still improving. Pulse 90, temperature normal. The swelling and pain were absolutely gone from every joint. On November 1st the pulse was 84, temperature normal. Convalescence was complete, and my visits terminated. A week later he walked to my house, a distance of half a mile, and he soon afterwards returned to duty.

He then goes on to say that it is now generally admitted that the exciting cause of acute rheumatism, as of pleuritis or pneumonia, is a chill; and that the effect is produced through the medium of the nervous system; and that, although the integument alone may be directly chilled, the deeply seated internal organs also suffer. The immediate effect of cold upon the nerves of the surface is to lower their functional activity, and to increase the action of the nerves of the internal organ in relation with that part; endocarditis thus becoming the first step in the development of acute rheumatism after exposure to cold. If it be physiologically true that, when two parts of the same body are nervously in sympathy with each other, if we produce a powerful action in the nerves of one, we may withdraw vital energy from the nerves of the other; then it follows that, when a derivative in the form of a blister is applied in the nearest vicinity to the endocardial lining when in an inflamed state, it is but carrying into effect the principle that counter-irritation is the most effective plan available to alter the excited condition of nerve-centres, and so to influence motor, sensory, and trophic nerves. Further, if experience tell me that counter-irritation over the heart is a potent remedy for the cure of acute rheumatism in all its phases, this fact will surely throw light on the nature of that disease. According to Dr. Peter Latham, "the treatment of diseases is in fact a part of their pathology. What they need and what they can bear, the kind and strength of the remedy, and the changes which follow its application, are among the surest tests of their nature and tendency." And Cullen, in the preface to his *Nosology*, page 16, says that "remedies cure diseases only in so far as they remove their proximate causes." When, therefore, a blister over the region of the heart cures endocarditis and its articular complications, it would surely not be unsafe to infer that the proximate cause is located in the heart itself.

If, then, it can be satisfactorily established that acute rheumatism may be cured by a topical remedy alone, what becomes of all the theories based on the idea of its zymotic, its constitutional, or autogenetic origin, and the sundry modes of treatment, and the antidotal remedies devised for the removal of the hypothetical condition of the vital fluid—eliminative, antacid, or otherwise? That it may be done— that it has been done in a number of cases—I have satisfied myself, and knowing how prone human nature is to self-deception, I have guarded against the personal element by inviting the presence and coöperation of several medical men of the highest ability and scientific acquirements as witnesses.

My chief desire is, that my simple plan for the cure of rheumarthritis shall be thoroughly tested

by the profession at large; of its efficacy, my own experience, and that of a number of my professional brethren, assures me. I cannot expect, however, that every one who may be equally convinced by personal trial and experience, shall also accept my explanation of its *rationale*. The pathology and physiology of the nervous system are not yet established on sure grounds; its supposed laws are subject to many contradictions, which only a more extensive knowledge of its principles, and their application, can elucidate. Nor would I wish to appear as proclaiming its efficacy in every case. I am satisfied, indeed, that endocarditis will still claim a place in the sad category of fatal diseases; but I also feel that, in cases possible of cure, the abortive plan proposed must claim precedence as the most rapid, safe, and permanent; from its very nature, the most potent to anticipate or remedy functional or organic disorder in the heart and its appendages. One other important result is likely to flow from its general adoption, viz., the reduction to very moderate dimensions of that class of applicants to whom the physician has so often reluctantly to refuse the benefits of life insurance, on account of the existence of permanent cardiac injury, caused by undetected lesion in cases of ordinary acute rheumatism.

Testes in Perineo.

The *Lancet* says that Dr. S. Baudry has recently met with a case of the rare malformation in which the testicle, instead of descending into the scrotum, passes down into the perineum. The subject of the deformity was a new-born child, in other particulars well developed and well nourished. The right testicle was found two centimeters in front of the anus, and the same distance outside the ano-scrotal raphe; it presented normal characters, being slightly smaller than the one on the opposite side; the vas deferens was readily traceable up to the external abdominal ring. This testicle was covered by normal skin. The right half of the scrotum appeared to be absent; the raphe was seen on the right side, and from it the skin continued, without fold or line of demarcation, to the thigh. No sign of any dartos could be found to the right of the raphe, for while cold caused distinct contraction on the left side none was observable on the right. The displaced testicle was not movable. In this the case differs from others that have been recorded, for in the accounts of such cases it is usually stated that the testicle was readily moved up into the groin, and in some it always assumed this position in sitting and walking, and all the treatment required has been to fit on some form of suspensory bandage to keep it up in the groin. Hunter was the first to draw attention to this rare deformity of the testicle, and the difficulty he experienced in accounting for it has, in the opinion of pathologists, not yet been satisfactorily overcome. Mr. Curling, who reports more cases than any other observer, attributes it to the action of a gubernaculum testis, of which the middle slip is attached to the perineum instead of to the bottom of the scrotum; and there is certainly much to be said for this view, the strongest piece of evidence in its favor being the fact that in a case in which Mr. Curling attempted to replace the organ he found a very firm band attaching its lower end to the superficial structures of the perineum. On the other hand, some authorities doubt whether the gubernaculum testis is the cause of the descent of the testis, and whether, therefore, its faulty attachment can lead to a misplaced testicle. In only a minority of the recorded cases has the corresponding side of the scrotum been absent, so that we cannot attribute the deformity to want of development of the normal receiving pouch. More frequently the scrotum is shrunken, and in two cases Mr. Curling and Mr. James Adams attempted to replace the testicle in its proper scrotal pouch. Mr. Hutchison has seen a boy with both testicles in the perineum. Vidal observed it in two brothers. It is well known that testicles retained in the abdomen usually fail to secrete spermatozoa. Such appears not to be the case when the organ reaches the perineum; in one case Ledwich dissected a specimen, and although the organ was small and soft, its ducts were found to contain spermatozoa. The most important question is that of the proper treatment. There is no evidence to show that the testicle is, in these cases, specially prone to become the seat of malignant disease, nor associated with hernial protrusion. When it is movable a retentive apparatus, which keeps it out of the way of injurious pressure during sitting, riding and walking, answers all the indications. In such a case as Dr. Baudry's, where the organ is fixed, it would be wise to wait to see whether it may not become mobile, but should this not occur it would undoubtedly require excision, as it would be constantly exposed to injury in sitting or riding. A case is recorded in which a perineal testicle became affected with gonorrhœal inflammation, and was almost incised, in error for an abscess. Zeiss mentions the curious coincidence of this deformity in a boy suffering from stone in the bladder, and the misplaced testicle—the left—was only discovered when he was about to commence the operation of lithotomy. Its position was such that he was forced to cut on the right side.

The Inter-Convertibility of Zymotic Diseases.

In the course of an address delivered before the late meeting of the Canada Med. Ass., by the eminent physiologist, Dr. W. B. Carpenter (*Canada Lancet*), he said: "Sir John Pringle gave further the results of some observations which he (Dr. Carpenter) had always held to be of fundamental value, namely, the principle of the convertibility of certain forms of zymotic diseases to other forms, diseases which they were accustomed to regard as of a different type. At the conclusion of the rebellion of 1745, in Scotland, the troops were shipped off in little brigs. Some of the men were suffering under the mild autumnal fever. The brigs knocked about for six weeks, during which the men were enclosed under hatches, without ventilation. In consequence of the unsanitary conditions, the fever changed, by the process referred to, into a

malignant typhus. They landed and the disease spread among the villages in which the men located. Another instance had come under his observation, of the malarious fever of the west coast of Africa changing, under similar conditions, into yellow fever of a contagious character.

Dr. McWilliam and others had reported similar cases of the same convertibility of these kinds of fever. He also referred to Sir Robert Christison's opinion in favor of the convertibility of zymotic diseases, and that typhus and typhoid could not always be distinguished, and said that Sydenham, one of the best observers, did not distinguish between scarlatina and measles. He also quoted Pasteur's opinion to the effect that the medium in which the germs were developed would have a most important effect on the germs themselves; that when germs which would produce ordinary malarious fever developed themselves in blood which was rendered unhealthy by bad ventilation or other causes, these germs would develop themselves in quite a different form, producing a different type of disease.

The smallpox epidemic which swept over Europe and America in 1871 was of a most singular character, and called attention to a type of smallpox which had not been epidemic since the beginning of the last century. He believed that the revival of the severe form in 1871 was due to the crowding together of the French army in Paris, and of the French prisoners taken by the Germans, and that the malignant type was thus developed out of the milder form. The lesson they had to learn from all this was to insist upon vaccination. Good vaccination might be said to be an almost perfect preventive. Another fact which the older practitioners recognized was, that the quality of the vaccination had deteriorated during late years, and the only remedy for this was to obtain the vaccine fresh from the animal.

Removal of Part of Appendix Vermiformis from a Hernial Sac.

Dr. C. R. Thompson reports the following case in the *British Medical Journal*:—

T. T., aged 57, a pork butcher, accustomed to heavy lifting, a well nourished and healthy man, had suffered for about twenty years from right inguinal rupture, for which he had worn a truss. On the morning of July 20th, he put on his truss as usual, but, on coming down, found himself in great pain, so that he took off the truss, and immediately a large swelling appeared at the seat of rupture, with pain so acute that he lay down, writhing, on the floor. He went to bed again, applied hot fomentations, and in the evening, feeling no better, sent for me. I found the right side of the scrotum occupied by a hard mass, oblong, having the appearance of a large inguinal hernia, very hard and firm, but elastic to the touch; no gurgling or movement in it; no impulse on coughing. Pressure and handling the tumor gave him pain; and the right iliac region was tender and painful. He had not vomited, and some castor-oil taken in the morning had acted freely during the day. Tongue furred; skin cool; pulse 72. He told me that the hernia had often come down on exertion, with the truss on; but that, until this morning, he had always found it soft, gurgling under the fingers, and easily reduced. I ordered him to continue the fomentation, which comforted him; to take half a grain of extract of belladonna every two hours, with milk and soda-water as nourishment. On July 21st, the night had been restless, with much pain in the right iliac region and in the swelling, which was unchanged, except in being more tender on pressure, and with more œdema of the scrotum. The bowels had acted at 3 A.M.; he had no vomiting; the pulse and skin were natural. The same treatment was continued. On July 22d, the night had been bad, with more pain and tenderness in the parts, and a distressed expression of face. There was no vomiting, and no further action of the bowels since 3 A.M. yesterday. The pulse and skin were natural. At 11 A.M. my brother saw the case with me, and we decided to cut down on the hernia; as, although there was an absence of vomiting, and, perhaps, of obstruction, there was evidently a strangulated mass, and commencing peritonitis. Under chloroform I dissected down to the sac, and, on opening it, a little turbid, pink, serous fluid escaped, of slightly feculent odor. The sac was occupied by a hard, solid substance, of about the size of two large fingers, of bright red color, and irregular, nodulated outline; it looked somewhat like three or four cock's combs strung together, the irregularities being partly covered by a thin layer of recent lymph. There was no bowel in the sac, and the fingers could be passed through the ring without difficulty. Thinking that it was probably a mass of diseased omentum, I cut away as much as could be easily protruded through the wound, the section being through a solid substance, like a fibrous tumor. The part removed was about two and a quarter inches long. The wound was brought together with sutures, and covered with a lint compress. The cut surface of the substance removed showed the orifice of a tube, about the size of a goose-quill, imbedded in a hard, dense growth. The corresponding orifice of the upper part of this tube, similarly imbedded, was visible in the wound. On passing a director down the duct, in the part removed, and slitting it open, I had no doubt that it was the appendix cæci, this being made more certain by finding at its extremity, buried in the mass, a small, sharp, rough piece of bone, which had probably been involved in the duct and caused the inflammatory diseased growth. The man recovered without a bad symptom.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The very important studies of Drs. Oscar Loew and Thomas Bokorny, of Munich, on the chemical conditions of life, have met with such attention that they have published a second and much enlarged edition of their essay, this time

with the title *Die Chemische Kraftquelle in Lebenden Protoplasma.* As we have previously explained, their theory is that the force of life lies in the energy of the aldehyde group, and that simple alterations in the organic conditions of protoplasm are sufficient to explain what was once called the *vis vitalis.* Their observations are ingenuous and interesting.

——Dr. C. L. Dana, in an interesting brochure, discusses "The Digestive Power of Commercial Pepsin in Artificial Digesters and in the Stomach." His conclusion there is this :—

A physician in giving a dose of *good* pepsin may believe that it will have a value two or three times greater than that exhibited under ordinary artificial conditions, *i. e.*, it will digest twenty or thirty times its own weight. This conclusion is in harmony with much clinical experience, that *good* pepsin has a *real* though not a *great* medicinal value.

Points of practical importance are, that large doses should be given, even of so-called pure pepsins. The physicians should always know how much pure pepsin there is in the saccharated preparations. Acid should generally be given immediately before, and the pepsin after meals.

——Anything that Dr. J. M. DaCosta writes on tubercle deserves the most attentive consideration, for there is probably no member of the American profession who has given this subject more conscientious study, and certainly there is none who feels more deeply the importance of presenting to the public only well matured opinions. We would recommend, therefore, a careful perusal of his pamphlet, entitled "Some Points in the Pathology of Tubercle (copies, we presume, may be had from Collins, printer, 705 Jayne St., Phila.). It is chiefly concerned with the relation of caseous pneumonia to tubercle.

BOOK NOTICES.

Index Catalogue of the Library of the Surgeon General's Office, U. S. A. Vol. III.

This very valuable work is progressing as rapidly as the appropriations permit. Every one who is interested in medical literature, or in the study of any branch of medical science, cannot but wish that the means were at hand to finish it completely and promptly. Its numerous references will save years of labor to the earnest student, and offer a ready means to ascertain what has already been done by previous workers in science.

The present volume extends from the word *Cholecyanin* to *Dzondi*, so that it is evident, in spite of its 1020 large, double-column quarto pages, that we have long yet to wait before we can see the work completed, even under the most favorable auspices.

The more closely we examine the way the work upon it has been done, the more are we impressed with its thoroughness and accuracy. It is really a miracle of painstaking, literary and typographical completene .

A System of Surgery : Pathological, Diagnostic, Therapeutic and Operative. By Samuel D. Gross, M.D., LL.D., D.C.L., etc. Sixth edition, thoroughly revised and greatly improved. 2 vols., pp. 1194, 1174; half Russia. Henry C. Lea's Son & Co., Philadelphia. 1882.

This work is really an extraordinary monument of learning and industry, especially when we consider that it is substantially the labor of one man. We do not hesitate to venture the prediction that it is the last complete system of surgery, based on the studies and observation of one individual, that the world will ever see. From this time forward, such is the rapid extension of that science, no one man will be able to grasp it in its entirety, and speak of all of its branches from personal knowledge. Humboldt predicted that no one could ever again attempt the writing of such a work as the *Kosmos*, and already his prediction is recognized as true by all naturalists. Coöperative labor must in future take the place of personal encyclopædic knowledge. We regard Gross' system of surgery, therefore, not only as a singularly rich storehouse of scientific information, but as marking an epoch in the literary history of surgery.

With regard to this present edition, it has received the most careful revision by the eminent author himself, assisted in various instances by able specialists in various branches. All departments of the vast and ever increasing literature of the science have been drawn upon for their most recent expressions. The illustrations are over 1600 in number, about 600 of which have been prepared especially for these volumes. The late advances in surgical practice have been carefully noted, such as the recent developments of Listerism and the improvements in gynecological operations. The novelties in pathology are recorded, and full justice is awarded to the labors of the numerous energetic younger workers in the various specialties of surgery.

The publishers have done their part in the most satisfactory manner. The paper and printing are beyond criticism, and the two volumes can be had, bound in half Russia, in the most durable and handsome style. In every respect the work reflects lasting credit on American medical literature.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D.,
JOSEPH F. EDWARDS, M.D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

POST-GRADUATE INSTRUCTION IN PHILADELPHIA.

Our respected contemporary, the New York *Medical Record*, has surprised some of us who dwell in Philadelphia by publishing a recent editorial, claiming that "It is eminently fitting that New York, the acknowledged medical centre of the country should be the chosen field for taking the *initiative* of the post-graduate movement." We would draw the attention of the writer of the article above quoted to the fact that for more than a year an advertisement of the Post-graduate Course in the University of Pennsylvania has appeared in the columns of the same journal, and in other medical periodicals in the United States. Philadelphia shelters the oldest and most widely known medical college in the country, and has produced a corps of writers whose works have become standard in medical literature; moreover, its hospital, and dispensary facilities are unrivaled. When the proposition was made to organize a post-graduate course, it was designed to benefit physicians who had been for many years coming to Philadelphia to pursue special courses of study under the care of physicians of repute in special branches of medicine. Few changes have been introduced in the character of the instruction. The scope of teaching has been enlarged by arranging individual workers into classes. The advantages given in the present post-graduate courses are the conservation of the practitioner's time by a well planned schedule and by the nucleation of several distinct lines of study under a reduced fee, offered as an inducement to both practitioner and instructor. At the same time, no practical detail is omitted which has made the previous isolated post-graduate courses so popular. Experience has shown that one of the most obvious necessities to perfect post-graduate instruction is a limitation in the number of attendants upon each class, and this has been fully appreciated, at least in the post-graduate courses in the University of Pennsylvania.

The pivotal point must always be to subordinate didactic instruction, so that it shall merely fill in the gaps in a full clinical course. The real needs of the practitioner are met by placing before him the cases of disease and the instruments for treatment and diagnosis, under the superintendence of competent instructors. The heart murmur, the fracture crepitus, the use of instruments of daily service in gynecology, are all taught by the personal examination of patients, while, in addition, the public, general, "old-fashioned" clinics, are still available.

Ward class instruction of under graduates in some medical colleges consists in the training of students in small groups, in the observation of disease and in the use of instruments of precision in diagnosis and treatment. By this measure, early practiced in Philadelphia, an impulse has originated which was recognized in the homes of students everywhere. Few men can practice medicine actively five or more years without gaining a knowledge of their shortcomings. These are almost entirely in the direction of the clinical study of disease in its wider and more comprehensive sense. Many of the

associates of our recent graduates will find the insight more and more painful by contrast, and a desperate effort will be made by many physicians in our great country to seek the medical centres for a review of old truths and the acquisition of fresh knowledge.

We may further add, not as a matter of boasting, but as a fact in the medical history of this country, that the first advocacy of the establishment of a post-graduate course in the United States, was in the editorial columns of the MEDICAL AND SURGICAL REPORTER.

It is perhaps a little too much the habit of our New York friends to be, or to profess to be, in very complete ignorance of the fact that they are by no means always leaders in matters of intellectual progress. When the facts are against them they go on the principle, "so much the worse for the facts."

THE FEES IN THE PRESIDENT'S CASE.

The public is at present being treated to a discussion about the fees of physicians and surgeons in connection with those handed in by the attendants on President Garfield. More than one of these has felt it incumbent on him to present the matter to the public in statements in the daily papers.

The amount of the fees indicate how wide is the range placed upon the value of their services by different professional men. One of them asks just double the amount of another, who furnished equal services and is not less competent in all respects. Another puts his claim—with characteristic modesty—not in figures, but relatively, by saying that he is entitled to twice the fee of any other medical man in attendance.

It is obvious, from the amount of money placed at the disposal of the committee, that Congress did not contemplate paying claims of any such magnitude as have been put in. Probably the public also are of this way of thinking. They certainly are, if we may judge by the comments of the press. These are, generally, to the effect that the bills for professional services are, in the aggregate and in certain items, excessive, if not extortionate.

Certainly there has never been, in the history of the country, any case, either in public or private life, where anything like such an amount has been claimed by the medical attendants, and to say the least, it does appear in an unfortunate light that the national disgrace of such an assassination should be followed by an unpleasant appearance of professional grasping. It would have been much more dignified for the whole question of professional remuneration to have been left to some of the eminently respectable and judicious medical bodies in this country to determine.

Speaking in a general way, the basis on which such a body would found its decision would be the average value of the physician's time, as shown by his annual income. In the case in question there were no serious operations performed, and nothing was done that tasked the skill or knowledge of the attendants. It was a case of gunshot wound, which ran an ordinary course, and was not interfered with. The unusual responsibilities and anxieties on account of the distinguished rank of the patient, about which considerable has been said, did not fall heavily on any single individual, as they were only too eagerly sought after and divided up. Moreover, practically speaking, they were more than compensated for by the eclat which the fact of being called in attendance reflected on the reputation of those whose advice was asked.

It is unfair, however, to bring into the estimate, as some newspapers have done, the fact that all these attentions did not save the patient: nay, that it has been publicly asserted by leading surgeons in this and other countries that grave errors of diagnosis and treatment were committed; because, as we have heretofore said, such statements cannot be proved, and if proved, no surgeon pretends to constant success or infallibility. If there were such errors, they were honest ones. The total amount of the fees claimed by the physicians is $85,000, or, including the relative claim $110,000—considerably more than $1000 a day. In spite of our desire to support the profession in its just rights, we acknowledge that this staggers us.

THE SIGNIFICANCE OF ALBUMINURIA.

In this issue we present an unusually interesting lecture by M. Dreyfus-Brisac, on albuminuria.

Of all questions now before the medical profession, none possess more practical interest than that of the etiology and significance of albuminuria. It is but a short time since the presence of albumen in the urine was regarded as a very conclusive indication of organic disease of the kidney.

We now know that it may occur where the kidneys are perfectly sound, while, on the other hand, the most serious pathological derangement of these organs may exist, while not even a trace of albumen can be found in the urine.

Thus has one of our strongest diagnostic points (as we supposed) in Bright's disease been toppled from its supremacy, and relegated to the position of a collateral symptom that may or may not be present, and to which we now attach very little importance.

What, then, is the significance of albuminuria? That is just the question that the scientific minds in the profession are now endeavoring to determine, and it is to this end that we desire to direct the clinical thought of our readers.

If the theory of Semmola be true, if albuminuria is the result of such changes in the albumen of the blood, as to render it unfit for assimilation, then it must be *excreted*.

If, further, this excretion causes irritation, with subsequent inflammation and degeneration of the kidneys, then have we a clue, a vantage ground, from which to push onward, in our researches into the therapeutics of Bright's Disease.

For if this abnormal albumen is the direct cause of the disease, then it would logically follow that, by preventing this change, or at once remedying it when it has taken place, we would necessarily remove the cause.

But this theory has not been universally accepted.

It is not incompatible with the mechanical theory, since the two conditions could readily be present at the same time.

What we want is additional research, to establish or dismiss this very plausible and acceptable theory. If established on a foundation of facts, then we must determine the nature of the alteration of the blood albumen, and when this is done, devise some means to prevent or remedy it. While carrying on such observations, a point of great practical value would be, to endeavor to ascertain what symptoms would make known this abnormal condition of the blood albumen in its incipiency, before it had commenced its deadly work on the kidneys. With such a combination of knowledge we would be enabled to direct the ounce of prevention for Bright's Disease, with almost unerring certainty.

There can be no question but that Bright's Disease is considerably on the increase in this country, and since it is very rarely (comparatively speaking) noted among those who live in every way a *natural* life, therefore does this one fact lend practical force to any theory of causation based upon derangement of the nutritive processes.

This terrible disease annually destroys *prematurely* so many *valuable* lives, deaths that leave an almost irreparable void, that to any one who can carry out successfully such scientific investigations as we have hinted at, the whole world will owe an eternal debt of gratitude.

DOCTOR OF MEDICINE, UNITED STATES OF AMERICA.

From the *British Medical Journal*, we learn that a Mr. Hubert Baynes Scott, was recently summoned before the Coroner at Deptford, and interrogated on a charge of malpractice preferred against his assistant, who was unqualified.

When asked, what is your qualifications? Mr. Scott answered, I am L. S. A.

The Coroner then asked him, "do you, therefore, consider yourself entitled to put M.D. on your card?" To which he replied, "I am a Doctor of Medicine, United States of America." We relate this case, because we wish to say to the profession of England that we have no such title in this country as that mentioned.

If the party in question desired to convey the idea that he had received a diploma from some University in the United States, he should have been more explicit. The general title he uses has no existence whatsoever in this country.

Notes and Comments.

Lawn Tennis Arm.

In connection with the "Rider's Sprain," to which we have had occasion to refer, the following case, recorded in the *Lancet*, by Dr. C. Sutcliffe, will possess interest:—

Mr. G. W., last winter, during a very hard-fought game of racquets, suddenly, after a back-handed stroke, felt severe pain over the pronator radii teres, which incapacitated him from taking further interest in the game, because, as he described it, he could not hit a single ball. There were swelling and tenderness on pressure along the course of the pronator. Cold water bandages, and subsequently soap liniment, gave relief. He can now play cricket and bat half a day without the slightest inconvenience, but if he plays lawn tennis for an hour, the muscle gets so painful and stiff that he can scarcely use his arm. As in the former there is no back-stroke, it proves pretty conclusively that the back-stroke is the cause of the injury.

It is well that we should study the various forms of accident to which our sports and pastimes may give rise.

Treatment of Athrepsia.

M. Parrot, of the Paris Faculty, has applied the designation athrepsia to a state of general constitutional debility in young infants, which, in its gravest forms has a duration of but ten or twelve days in the acute state, and of fifteen or thirty in the chronic.

The first great rule of treatment in this condition is simple: Suppress every form of alimentation except the breast milk. This is the principal point, and if the nurse is not good, an immediate change must be effected; an athrepsic child deprived of breast milk will inevitably die. Pharmaceutical treatment is of much less importance.

Against the diarrhœa and colic so common among infants, the following potion may be given by teaspoonfuls:—

℞.	Bismuth subnit.,	ʒ ss	
	Syr. simplicis,	ʒ j	
	Aquæ calcis,	ʒ j.	M.

This potion may be freely used each time the infant is put to the breast, and the dose doubled if it be four or five months old. When the tongue is much furred a mild emetic of syrup of ipecac is of great service. Castor oil is the best purgative at this period of life.

Against protracted vomiting, M. Parrot administers cold drinks, iced milk with the addition of half an ounce of brandy or rum to the nursing bottle of milk.

The brandy may be replaced by elixir of pepsin. While cold drinks are administered, the infant should be kept very warm; he may be placed in a mustard bath and well rubbed, then laid between warm blankets. If any aphthæ appear, either of the following lotions may be applied:—

℞	Sodæ borat.,	ʒ iss	
	Mel. rosæ,	ʒ ss.	M. Bene.
℞.	Potass. chlorat.,	ʒ iss	
	Glycerinæ,	ʒ ss	
	Mel. rosæ,	ʒ ss.	M.

Nerve Stretching.

The following interesting cases are described by Dr. Doutrelepout, in the *Cbl. f. Klin. Med.*, 1882, No. iv, as a contribution to nerve stretching in spinal diseases:—

In a man, aet. 31, suffering from chronic myelitis (paraplegia and anæsthesia of the lower limbs, loss of patellar-reflexes, disturbances in micturition, etc.), D. stretched, in four different operations (on account of a valvular lesion, only local anæsthesia was made use of), both sciatic nerves and crural nerves, within a period of five weeks. The difficulty in urinating ceased, also the annoying sensation of a girdle around the abdomen; sensation became normal, motion returned in the legs, though the patient had still to use crutches, threw his legs forward, and still trembled.

In a case of tabes, after four years' existence, after stretching of the four large nerves of the legs, the ataxia, the girdle sensation and, in the beginning, also the pains, improved; later, however, the pains returned, but with less intensity. In a second case of locomotor ataxia, which had lasted over two years and a half, after stretching of both crural nerves, the ataxia became less and the pains ceased totally.

From all the reports of nerve stretching in spinal diseases so far published, we come to the conclusion that no case of lesion of the spinal cord should be given up as unamenable to treatment, without first nerve-stretching, and if neces-

sary, of both sciatic and crural nerves, having been tried, but under antiseptic precautions. There is almost no case on record where some of the symptoms had not improved, for a short time, at least.

Morphia Poisoning.

In the *Lancet* Dr. Philip E. Hill reports the case of a man suffering from mitral disease, to whom he gave a hypodermic injection of $\frac{1}{3}$ of a grain of morphia, to relieve severe abdominal pains, for which chloral and bromide of potassium had been useless. The man immediately went into a sound sleep, and when again seen (five hours later), was comatose; eyelids open, pupils contracted to a pin point and insensible to light, extremities cold and surface of body clammy; respiration slow and stertorous, but pulse unaffected. The usual remedies for morphia poisoning succeeded in restoring consciousness, and the next day all bad symptoms had disappeared. The question arises, why such a small dose should have produced such grave symptoms. Dr. Hill was sure of the strength of the solution used, and plenty of time had elapsed for the elimination of the chloral.

Cutaneous Injections.

Under this title Dr. Walter Scott makes a very sensible and practical contribution to the *Lancet*. He suggests the experimenting with injections, to endeavor to produce a condition of the blood unfavorable to the development of disease-carrying bacteria. We have all heard that the injection of a solution of permanganate of potash into a vein, immediately after the introduction into the system of the rapidly fatal cobra poison, prevents that poison from having its usual fatal consequences, and doubtless it would have the same result if injected immediately before the bite of the cobra. Again, Dr. Fontaine, Bar-sur Seine, has had the most remarkable success in his treatment of diphtheria, by giving his patients sulphide of calcium until the breath and skin exhale the odor of sulphuretted hydrogen. And even if the experiments on animals, such as I suggest, should fail to discover an antidote or germicide powerful enough to counteract the poisonous effects of the micro-organisms, which in a concentrated form are injected under an animal's skin, it might still be possible for those of our surgeons who have a large and sad experience of blood-poisoning, or for those practitioners who have numerous cases of zymotic diseases constantly under their charge, to move in the track of those gentlemen who have been successful in combating the deadly cobra poison, and the too often fatal diphtheria.

There are several antiseptics besides permanganate of potash with which the blood might be saturated, either by injection into a vein, or by small and frequently repeated doses, for example, eucalyptus, sanitas, the sulphides, the carbolates, the salicylates, etc.

Blood Diet.

As the result of five years' experience at the Royal Hospital for Children and Women, Dr. Ed. O. Day gives, in the *Lancet*, the following mode of preparing blood as a diet for delicate children:—

A given quantity of blood is collected, and before coagulation takes place, is mixed with three parts of water, and kept in constant movement for some time, then gradually evaporated over a water bath, at a temperature not exceeding 100° F. Very great care has to be taken to prevent coagulation. When the consistence of chocolate is reached, a higher temperature may be used, to perfect drying. It should be reduced to a powder in a mortar. It is like coffee, with very little taste, but with a peculiar odor. If properly prepared it should be perfectly soluble in water. He commences, for a child one year old, with a teaspoonful during the day.

Palpitation of the Heart.

The *British Medical Journal* says:—"In the Appendix to the British Army Medical Department Report, Dr. Veale has given a summary of the ascertained or most probable causes of palpitation in the cases he has examined. Of these, malarial fever ranks highest, followed by intemperance, heat of climate, marching on active service, exertion generally, excessive smoking, hardships on active service, and several minor causes. He does not consider that the pressure of the valise or of the belts now occupies a prominent place, as it formerly did, although it may still contribute. He speaks very decidedly of the injurious effect of excessive smoking, although he hardly assigns to it as high a place among the causes as we should be inclined to give it, especially when combined with drinking. But it is a cause which it would be extremely difficult to abate, though probably something might be done in the way of issuing less "villainous stuff" to the soldiers than they are in the habit of smoking. "The soldier loves his pipe, and its value as a 'carebreaker' may

be, and I dare say is, very great; much caution would therefore be needed in any attempt to curtail this luxury, but in the meantime it would certainly be good economy on the part of Government to insist that such a deleterious substance as the 'twist' or 'stick' tobacco should never be sold in canteens, or issued to the troops on board ship, or in the field." If any one doubts the injurious influence of this tobacco on the heart's action, we recommend him to test it by taking the sphygmograph tracings of even an habitual smoker, before and after indulging in a pipe of it."

The Employment of Blisters on Children.

The *Medical Times and Gazette* quotes from a lecture on this subject, by Dr. Archambault, delivered at the Hôpital des Enfants Malades, which concludes with the following advice:— "If I am still in doubt regarding the good effects which I have believed might be attributed to blisters under some rare circumstances, my conviction is absolutely final as to their mischievous influence in a great number of cases; and, in a more concise manner, I may say that I am not sure that I have ever seen them do any good, but that I am very certain that they have often done a great deal of harm. Never apply them, then, in children, unless they are positively indicated, and especially take every precaution to prevent the accidents to which they may give rise."

A Proposed Modification of Esmarch's Method.

The London *Medical Record* says that Szydlowsky proposes a modification of Professor Esmarch's method of obtaining artificial bloodlessness, which consists in preparing a piece of India-rubber tubing, much after the fashion of the rings which are placed round horses' fetlocks to prevent galling, and rolling this ring up the extremity from the periphery, driving the blood backward, and then leaving the ring *in situ*, with the intervention of a wad of lint to act as a compress over the artery at some point opposite a bony prominence. The advantages he claims for this method are: greater rapidity of application; its cheapness compared to the real Esmarch's bandage; lighter weight, therefore greater transportability in the field (see Esmarch's article on the elastic girth as a tourniquet, and others of minor importance). [The method described by M. Szydlowsky is that which is adopted in Australia when producing artificial bloodlessness for operations, the impression there being that this was Esmarch's original method. The process was explained to the reporter 2½ years ago, by a young Australian medical man, who came to the British Isles for study, and wondered that Britain was so far behind as not to know the proper mode of applying Esmarch's apparatus.]

Important for Smokers.

In the chemical laboratory of the Board of Health, in Bremen, Dr. Kissling (*Deutsche Medizinal Zeit.*, Aug. 7, '82) has made investigations in regard to the danger of smoking cigars. It would lead us too far, were we to publish his careful experiments and analyses in detail, but we will give our readers the results of the same.

As grave poisons he found carbonoxyd, sulphuretted hydrogen, prussic acid, picrolin bases and nicotin. The first three cannot come into consideration, as they are too volatile, and present in too small quantities. Regarding the nicotin, however, he found that a very small trace only is burned up by the smoke, but that the stump becomes the richer in this narcotic substance, the larger the cigar is, the more the end is chewed, the shorter the stump gets, and the oftener the cigar is lit. Conclusion: to avoid all danger, smoke a cigar not too thick and long, don't chew the end, smoke only two-thirds of every cigar, and throw it away as soon as relighting becomes necessary. Never smoke a cigar after it has once gone out. *Cigarettes are the least injurious* of all tobacco smoking.

The Education of the Young.

The *Lancet* says that M. Duvaux, Minister of Instruction in France, has addressed a circular to the directors of lyceums upon this subject. In it the system hitherto for the most part in vogue, of cramming the memory with dates and dry facts, is deprecated, while the professors are enjoined to devise methods which shall be calculated to draw forth the intelligence of the learners and foster their thinking powers.

Tendon and Other Reflexes.

The *Medical Times and Gazette* says that A. Eulenberg has made some observations in 124 children, varying in age from one month to five years: They were all healthy. The knee phenomenon was not obtained in 7 cases on either side, and in 3 on one side. The foot phenomenon failed, or was very indistinct, in 101 cases. The reflex from the tibia and radius

was wanting 108 and 109 times respectively. The abdominal, nasal, corneal, and pupillary reflexes were, on the contrary, always present. The auricular reflex was not clearly got 5 times. Out of 78 boys, 20 did not exhibit the cremasteric reflex. The period of latent stimulation of the foot phenomenon (Achilles tendon reflex) was found to be about one sixty-second part of a second longer than for the knee phenomenon.

Mixed Chloroform—Morphia Narcosis.

This method, as practiced by Prof. Thiersch, in Leipsic, succeeds frequently, without producing unconsciousness, in causing a perfect analgesia, during which Thiersch had made grave and prolonged operations.

To be certain of this narcosis, drunkards receive one-half to one grain morphia; men one-half of a grain; women one-quarter of a grain, and children one-twelfth to one-eighth of a grain. From 5 to 7 minutes after the hypodermic injection the patients are very lightly chloroformed, till near the stage of excitement; the operation is performed; as soon as pain is felt, a little chloroform is added. In this manner not the tenth part of chloroform is needed, the operation just as painless as under full chloroform narcosis, and there is no risk or danger incurred.

Mycotic Disease of the Kidneys.

In No. iv, of the *Ztschr f. Klin. Med.* p.,191, Dr. M. Litten reports two very interesting cases of mycotic affection of the kidneys. Two persons living together in one house became suddenly affected with rigors, great increase of temperature and albuminuria of a high degree. Under uræmic symptoms both died. Toward the end perfect anæmia was present. At the post-mortem the kidneys were found filled with bacteria. Both patients had been drinking water from a well which existed near a graveyard. The water was found full of bacteria. Similar cases have been reported this year by Bamberger and Aufrecht.

Nature's Removal of a Tumor.

A peasant woman, æt. 45, mother of three children, the youngest six years old, suffered for about a year from a hard, uneven tumor of the right mamma. The tumor had grown tightly to the skin, and in one place it showed softening and some fluctuation. The general nutrition had begun to suffer also. Dr. J. Stein (*Wratsch*, 16, 1882, a Russian paper) diagnosticated cancer, and proposed amputation of the breast. In the meantime he ordered subcutaneous injections of pyrophosphate of iron, with citrate of sodium ($\frac{1}{6}$), and administered one such hypodermic in her back. Two days later erysipelas migrans developed itself, and when this disappeared, twelve days later, only two little swellings of the size of a walnut were all that remained of the tumor, and at the same time the general health and nutrition of the patient improved directly.

Eccentricity and Idiosyncrasy.

Dr. William A. Hammond contributes a very practical article on this subject, to the New York *Medical Journal and Obstetric Review*. It is interesting and valuable as directing more thought toward the clinical value of carefully noting idiosyncrasies than has been hitherto the rule. He concludes that the idiosyncrasies of individuals are not matters for ridicule, however absurd they may appear to be. On the contrary, they deserve, and should receive, the careful consideration of the physician, for much is to be learned from them, both in preventing and in treating diseases. In psychiatrical medicine they are especially to be inquired for. It is not safe to disregard them, as they may influence materially the character of mental derangement, and may be brought in as efficient agents in the treatment.

Actions of Pepsin.

The London *Med. Record* reports the case of an old man of 80, who suffered from retention of urine, from the presence of coagulated albuminoid masses in the bladder. An injection of about sixteen grains of crystallized pepsin led, in a few hours, to a dissolving of the masses and relief.

Several observers have reported benefit from an acidulated concentrated solution of pepsin in diphtheria:—

℞.	Pepsin cryst.,	℥j	
	Acid. muriat. dil.,	gtt. xx	
	Aquæ,	℥j.	M.

Apply copiously every hour, with a throat mop.

The crystallized pepsin used is prepared by Dr. Carl L. Jensen, of this city, and we can add our testimony to its activity in this form.

Trichinæ in Adipose Tissue.

Contrary to the commonly accepted idea, that trichinæ inhabit only muscular tissue, the *Lancet* says that Chatin has found them in adipose tissue. That he did not mistake them, is evi-

denced by the coexistence of the same parasite in the muscular tissue of the same subject. Experiments proved that animals fed with trichinous fat exhibited no indications of trichinosis, while others fed with the flesh from the same infected animal quickly suffered and died with symptoms of intestinal trichinosis; although further observations on the comparative innocuity of the fat must be made before the fact can be regarded as of hygienic importance. The practical value of the discovery at present seems to be that the fat, as well as the flesh, of suspected animals should be examined.

Imperfectly Developed Child.

At a recent meeting of the New York Med. and Surg. Soc. (New York *Med. Journ. and Obstetrical Rev.*), Dr. S. O. Vanderpoel mentioned a case which he had seen. The fingers grew directly from the shoulders, and there was no scapula. The legs and feet were rudimentary. The child, a female, was living and healthy.

The Soy Bean.

The *British Medical Journal* says that Prof. E. Kinch, writing in the *Agricultural Students' Gazette*, says that the Soy Bean approaches more nearly to animal food than any other known vegetable production, being singularly rich in fat and in albuminoids. It is largely used as an article of food in China and Japan. Efforts have been made to acclimatize it in various parts of the Continent of Europe, and fair success has been achieved in Italy and France; many foods are made from it and its straw is a useful fodder.

A New Use For Salicylate of Soda.

Dr. Theo. M. Kendall writes to the *Lancet* that he derived most gratifying results in a case of severe chalk gout, from the use of a lotion of ten grains of salicylate of soda to the ounce. By its use, chalky deposits in the ear were softened, and in four days disappeared, leaving only a small scar.

Treatment of Enlargement of the Spleen.

The *Lancet* says that injection of drugs into the substance of the spleen has been lately tried as a means of effecting reduction, in cases of hypertrophy. Ergot and sclerotic acid have been used. Simple puncture, causing a hemorrhagic infarct, which by repetition might cause atrophic shrinking, has been tried. This, as well as galvano-puncture has not been successful. Fowler's solution has been used. The only success worth noting has been derived from the *internal* use of ergot, which has, in one case, acted very rapidly.

Chlorodyne to Control Diarrhœa.

At a recent meeting of the New York Med. and Surg. Soc. (New York *Med. Jour. and Obstet. Rev.*), Dr. Post related a case in which, after the induction of premature labor, an injection of half an ounce each of senna and sulphate of magnesia ($\frac{1}{3}$ of the mixture), was given to relieve obstinate constipation. It caused a persistent diarrhœa, which lasted more than twenty-four hours. Morphia and tannin, by the mouth, rectum and hypodermically, failed to check it. Chlorodyne was immediately successful. Dr Post was very much impressed with the remarkable effect which seemed to result from so small a dose of senna and magnesia.

The Effects of Muscarin.

The *Journal of Nervous and Mental Disease* says that Franz Hogyes has made experiments, with the following results:—

1. Muscarin increases the excitability of striped muscle-fibre.

2. It depresses very rapidly the functional activity of the central nervous system, and lessens the excitability of the peripheral nerves.

3. The dilatation of the blood-vessels after an injection of muscarin is an immediate result of the paralytic action of this poison on the vaso-motor center. Later, there ensues a depression of the smooth muscle-cells.

A Poison for Tubercular Bacteria.

The *Lancet* says that M. de Korab has cultivated the bacteria of tuberculosis in bovine blood serum, and after treating some of this preparation with *helenine*, it was found to have lost its infective properties, while similar material not exposed to this drug readily caused tuberculosis when injected into animals. We anxiously await further developments.

Quadruple Birth.

The *Union Médicale* reports the case of a woman who was delivered of three girls and a boy. The four children together weighed six kilograms and a quarter. Three were born dead and the fourth was very feeble.

Influence of Febrile Diseases on Syphili.

It is perfectly certain that several grave febrile diseases may modify the course of constitutional syphilis so as to change, or even cause the complete disappearance of, the external manifestations of the disease. Dr. Petrowski (*Vratsch*, No. 22) reports three cases of this description.

In the first the patient had contracted the chancre six months previous to entering the hospital. He had an indurated chancre of the prepuce, balanitis, mucous patches on the glands and scrotum, ulcerations in the throat coincident with a scaly, syphilitic eruption on the face and scalp. A six weeks' mercurial course produced but slight amelioration. While at the hospital he fell sick with the smallpox; the attack was of exceptional gravity, but when the crusts of the smallpox eruption had fallen, no trace of the syphilitic eruption remained; the patient was under observation for several years, and none of the syphilitic manifestations reappeared.

The second patient, who was also at the first period of the disease, was cured after a very grave attack of erysipelas of the face, which lasted fifteen days; he had never taken any mercury, and ulterior observation revealed no new manifestation of the disease.

The third case reported is less striking; the patient had a syphilitic gumma at the angle of the jaw, and after an attack of typhoid fever, this gumma suppurated, leaving a cicatrix which bore no resemblance to ordinary syphilitic cicatrices.

The Treatment of Diabetes.

In the course of an article on this subject, in the *Medical Annals*, Dr. F. C. Curtis, of Albany says:—

"A point not often enough spoken of is the value of *fresh air*. It is one of the most desirable things to secure, which my observation bears me out in saying. Keep them out of doors constantly. Along with this, muscular exercise short of fatigue. Remember the etiological factors; sedentary occupation and nervous depression or worry or strain are acknowledged as prominent. I do not speak from statistics, but isn't the disease one of city life, and not one of quiet, contented, out-of-door country living? Securing its features of fresh air, exercise and equability of mind are certainly most desirable features toward remedying this intractable disease."

These eminently true remarks only serve to more strongly impress the fact, that such a life is conducive to the most healthy existence of the normal individual, and is, therefore, of necessity, the life most calculated to enable the morbid organism to resist for the longest time, if not to cure, the ravages of any organic disease.

The Actual Cautery for Dermato-Cellulitis.

Dr. A. C. Post reported, at a late meeting of the New York Medical and Surgical Society, (New York *Med. Jour. and Obstet. Review*) a case of chronic traumatic cellulitis, in a man aged forty. The arm was greatly swollen and brawny and its movements were materially interfered with. Repeated blistering had produced some benefit. The actual cautery was applied at a number of points, and when reported (one week after operation) the inflammation had greatly subsided. Bi carbonate of soda dressings were used.

Plica Polonica.

It has been reported (we cannot say on how good authority), that a disease bearing this name has made its appearance in London, brought over by the traders in false hair from Poland. The hair, instead of dividing into fine threads, conglomerates into thick masses, with only one root, which bleeds on being cut, so that no relief can be obtained except by cauterization of the whole mass. The disease is considered incurable, and renders its victim a hideous object.

Division of Frœnum of Upper Lip, for Imperfection in Speech.

In the New York *Medical Journal and Obstetrical Review*, Dr. Post records the case of a girl aged six, who had difficulty in uttering the labial sounds. The mother directed attention to unusual shortness of the frænum of the upper lip, which was divided, with marked improvement.

Correspondence.

Death Produced, Probably, by a Small Dose of Potassium Iodide.

Ed. Med. and Surg. Reporter:—

The person to whom it was given was a woman of a frail, cachectic constitution, aged about 35, wife of an intemperate machinist, mother of about eight children, three or four of whom died in the early months of infancy; the last one perished in convulsions soon after birth, the causes of which I did not learn. Those who are living are apparently in perfect health.

The patient was under my care for two years almost continuously, for a complication of troubles.

Diagnosis.—Chronic, non-suppurative inflammation of both middle ears, destruction of septum narium and turbinated bones, tubercular deposit in the apices of both lungs, chronic laryngitis; digestive and procreative organs in a miserable condition.

Cause.—Probably a general tuberculosis; possibly syphilis. The last is mere surmise, no positive symptoms being present. At any rate, I decided to prescribe iodide of potassium in small quantities, about six grains three times daily, in syr. of orange peel and elix. of calisaya.

The patient was despondent in the highest degree, and no amount of cheering would raise her spirits at all. I urged her continuously, and insisted on the importance of living out of doors, but to no purpose. She would lie bundled up behind a hot stove, all the time in sweat, and at last she became so exquisitely sensitive that the least current of even warm air would almost certainly give her a "cold."

The day that the iodide was ordered was a cool and damp one; a pretty sharp westerly wind was blowing; that day she also came to my office. The medicine was taken at seven o'clock P.M., and she said that as soon as she had swallowed it a sense of suffocation came on, which lasted all night. Toward morning I was summoned, and made a diagnosis of spasmodic croup. The cause I considered to be the imprudent exposure. I never for a moment entertained the idea of the iodide being the cause. The spasm soon, however, subsided. In order to show them that it was not the iodide, I ordered the continuation of it, but, as I learned subsequently, she refused to take it.

Some three or four weeks after that her husband complained to me of his wife's seeing double, and sent her to my office. This day proved even worse than the one before, for which imprudence I gave her a sharp reprimand. A slight strabismus accounted, I think, for the diplopia. With still more determination I persuaded her to take the medicine; after a little urging she took a spoonful of it, and almost immediately commenced to breathe with difficulty, which kept increasing, in spite of all treatment, until next night, at 12, she quietly passed away. The iodide was prepared by Powers & Weightman, and contains a proportion of iodate. There are no impurities that the iodide might contain, to my knowledge, which would produce any such effect on the larynx. In view of the fact that the spasm of the glottis followed almost immediately on the taking of the drug, the apparent cause and effect being quite evident, I cannot abstain from the thought that it was directly instrumental in the causation of death.

If it were a mere coincident, it would be an exceedingly strange one, to occur as it did, perfectly alike after each administration. Exposure is very frequently productive of just such troubles, especially so in susceptible subjects, but, nevertheless, it seems that that cause cannot be held responsible for the disastrous effect. For, before she took it, her breathing was comparatively easy, both times, but immediately after it the dyspnœa commenced.

Dr. Tanner has reported several cases occurring in his own practice, of spasmodic croup after small doses, and one fatal case. Another man reports a case of œdema glottidis during the use of the iodide. This exceptional effect was in this case due to some idiosyncrasy of the patient, or some impurity in the remedy.

I would like to hear, through the columns of the REPORTER, if any of the readers have had any such experience with the article.

Beaver Dam, Wis. F. SHIMONEK, M.D.

Turpeth Mineral in Acute Laryngitis.

ED. MED. AND SURG. REPORTER:—

Under the editorial head of last week's REPORTER, an invitation is extended to physicians for contributions on the various subjects of medicine, etc. In compliance, I would simply direct attention to the use of turpeth mineral (Hydrargyri Sulphas Flava) in the treatment of acute laryngitis. It is an old remedy, very much in vogue during the antiphlogistic reign, and yet it has lost none of its virtues by its banishment. In this progressive age of new theories and new remedies, we have lost sight of a great many articles of medication whose reputation was undoubted until a false conservatism tabooed their use and placed them upon the superannuated list, for more pretentious articles. The fact is, we are prone to extremes, and in our eagerness to reach the other end, fail to exercise that caution that we should with regard to new theories and new remedies. We take it for granted that it is so, and proceed to sacrifice what unlimited experience had pronounced trustworthy for very much of what, as yet, lacks confirmation. Even now the "logic of events" foreshadows an era of yet more importance, than any of its predecessors; one in which microscopic fauna and flora will be made to play a very conspicuous part in the genesis of disease, and as a consequence, will require a change in its etiology as well as a new departure in its medication. Thus far I have kept pace in the progressive march, but while doing so, take a retrospective glance, to see how much I have gained. It is exceedingly hard to get rid of old habits. I have endeavored ever since the introduction of veratrum not to imbrue my hands with bloodshed; but the temptation is so strong that I cannot resist it when favorable opportunities present. So, too, of some of the old remedies that have been placed upon the retired list; I occasionally prescribe them, in full confidence that they will respond to their old reputation.

Three years ago we had much rainfall, and the following winter was an open, changeable one. So that the conditions for the production of diseases of the air passages were as favorable as could be. Among the prevailing ones to be encountered were numerous cases of acute laryngitis, which paid no deference to age or sex, and but little to treatment. I had used the ordinary mode of medication, together with topical applications of cold, medicated vapors and the warm bath, but failed to derive much benefit until this preparation of mercury was used, when it proved to be the remedy "par excellence."

Its alterative and emetic effect is well adapted for the resolution of the inflamed larynx, by unloading the congested capillaries, thus preventing submucous infiltration as well as laryngeal exudation. It must be given early in the disease, and in sufficiently large doses to produce emetic effects. If delayed until prolabial congestion and other symptoms of imperfect oxygenation have taken place, its administration, like all other remedies, will prove a failure. It is my first choice in all cases of laryngeal inflammation, and since I recommenced its use, I have been spared that horrid sight of witnessing "deaths in lingering torments, protracted to the last."

Bluffton, Ind., Oct. 27, 1882.

Oxide of Zinc in Epilepsy.

Ed. Med. and Surg. Reporter:—

When I commenced practice, in 1833, nitrate of silver was the grand remedy for this complaint. After repeated failures with it, I was told by Dr. Boyd, an octogenarian of our city, that he had no trouble in its cure. He had treated a man successfully, who had not earned a dollar in twenty years, who afterward supported his family. I gladly adopted his practice, and have been successful ever since. The remedy, oxide of Zinc. "Begin with ½ grain dose, three times a day for twenty four doses. Then one grain for twenty-four doses. Then 1½ grains, and so on up to 15 grains, three times a day, rubbing the spine with stramonium ointment, morning and evening, and other stimulating embrocations," which I have seen used. Since then I have been successful; never going beyond ten grains, except in one case, of a hard drinker and opium taker, who at the time I commenced with him had been treated for a year with bromide of potash, impairing his memory badly, which was restored by the use of zinc.

New York. Edw. Vanderpoel, M.D.

Cancer of the Pylorus.

Ed. Med. and Surg. Reporter:—

An article in the August 19th 1882 number of your journal brings to my mind a very similar case, I have frequently thought of reporting.

In June, 1874, a patient, O. M., white, male, aged about 50 years, came under my observation, having applied to my then partner, Dr. S., and myself for treatment for what he was pleased to call dyspepsia. The history that he gave was one of simple indigestion, troubling him for years. He had suffered at no time any acute pain. Had been frequently troubled with eructations of gas, and had often vomited his food with some relief. Had no excessive tenderness anywhere. Had taken many different kinds of medicines from many different kinds of doctors, with slight improvement, and then relapse, each time growing a little worse. Had finally visited the "Gibson Wells," near here, for relief from what he thought to be digestive derangements. Had found no benefit there, and came here, and, as said before, placed himself under our treatment.

A very careful examination of him threw but little additional light upon the history already given. He digested but little of the food he ate, vomiting most of it in a state of fermentation. Complained of no special pain; was peevish and fretful. Said that if his digestion could be improved he "would be well." At no time did we notice any coffee-ground material in the vomited matters. As in the case reported, at no time, "upon the most careful and repeated examinations," could any tumor be found, though the pulsations of the abdominal aorta could be seen through the walls of the abdomen. There was nothing in the case, except the continued vomiting, to point to cancer. Finally, the patient began to eject everything, in a short time after eating. Even water was retained only a few moments. No microscopic examination of the ejecta was made.

He died June 24th, 1874, a mere skeleton. On the day of his death the vomit was extremely offensive, having a fecal odor. A post-mortem examination was made on the next day, which resulted in finding the pyloric orifice of the stomach completely closed, as with a valve, by a scirrhous carcinoma.

There is the same peculiarity about this case that there was in the one reported in your journal, and one more; namely, no coffee-ground vomit, unless that on the last day could be so considered.

T. J. Happel, M.D.

Trenton, Tenn.

News and Miscellany.

The Cradle of American Medicine.

The following is from the Michigan *Medical News.* Philadelphians are now advancing reasons calculated to establish their city as the cradle of American medicine: The first practical instruction in anatomy in America was by Dr. Thomas Cadwalader, in 1750; the first permanent general hospital was founded there, in 1752; the first clinical instruction in America was given there by Dr. Thomas Hurd, in 1756; the first medical library in America was founded there, in 1763; the first medical society in America was organized there, in 1766; the first medical dispensary in America was established there, in 1786; and the first American medical college was organized there, in 1765.

Action of the Philadelphia County Medical Society with Reference to the Army Medical Museum and Library.

At the last stated meeting of the Philadelphia County Medical Society, Dr. Wm. M. Welch offered the following preamble and resolutions, which were unamiously adopted:—

Whereas, There is reason to fear that at the next session of Congress an effort will be made to destroy the identity of the great Medical Museum and Library at Washington, by merging them into the general Congressional Library and placing them under the control of the latter; and

Whereas, Under their present management

this museum and library have grown to be the most valuable collections of their kind in the world, and are consequently, of incalculable value to the cause of medical science, thus rendering their preservation and progress objects of deep interest to the medical profession of this country, therefore,

Resolved, That the Philadelphia County Medical Society earnestly, but respectfully, request the Honorable Senators and Representatives of Congress to make no change in the present management of the Army Medical Museum and Library, but would earnestly urge upon Congress the importance of providing a commodious fire-proof building, in Washington, for better preservation and protection of these invaluable collections.

Medicated Soaps.

The *Chemist and Druggist* says that the *Seifenfabrikant* gives the following recipes for the manufacture of Medicated soaps :—

Tannin Soap.—9 kilos. of cocoanut oil are saponified with 4½ kilos. of soda lye, then 250 grammes of tannin, which has been previously dissolved in spirits, are put in and mixed. The soap is perfumed with 30 grammes Peru balsam; 10 grammes cassia oil ; 10 grammes oil of cloves.

Iodine Soap.—10 kilos. cocoanut oil, 5 kilos. lye at 38° B., 1½ kilos. of iodide of potassium, dissolved in 1½ kilo. of water.

Gall Soap.—1½ kilo. of galls are stirred in 25 kilos. of melted cocoanut oil, and the latter then saponified cold with 22½ kilos. of soda lye at 38° B. The soap is colored with 350 grammes of ultramarine green, and perfumed with 75 grammes lavender oil, 75 grammes cummin oil.

Camphorated-sulphur Soap.—12 kilos. of cocoanut oil, 6 kilos. of soda lye of 38° B.; 1 kilo. of sulphate of potassium, dissolved in ½ kilo. of water ; 160 grammes of camphor, which is to be dissolved in the melted cocoanut oil.

Chicory: A New Source of Alcohol.

According to *Erfindungen und Erfahrungen* that celebrated coffee substitute, chicory, seems likely to become of importance as a source of alcohol. The root contains an average of 24 per cent. of substances easily convertible into sugar, and the alcohol obtained by its saccharification, fermentation and distillation, is characterized by a pleasant aromatic taste and great purity.

A Graceful Tribute

The reception given by Drs. Sims, father and son, to Professor S. D. Gross, on Thursday, November 2, in New York, was a graceful tribute to a distinguished citizen and scientist by a lifelong friend and his son. The social gathering was brilliant, and the occasion was in every respect one to be long remembered. The most eminent members of the profession from the adjacent cities were there, and the evening passed off with the utmost satisfaction to all.

Southern Illinois Medical Association.

The Southern Illinois Medical Association, which numbers about two hundred members, will meet in Anna, November 15th and 16th. The meeting promises to be one of the best in the history of the organization. All members of the regular profession are cordially invited to attend. J. I. Hale, M.D., *Secretary*.

Items.

—Crude acridine, one of the heavy tar oils, is said to be an insecticide.

—A patent has been taken out in Cuba, for the manufacture of soap from the dregs of molasses. The soap so made is said to be very good and extremely cheap.

—The poison of the Borgias, according to an old Italian manuscript, was the fatty principle of ergot of rye, obtained by maceration in putrefied (ammoniacal) human urine.

—Hæmophilia is said, by the *British Medical Journal*, to be the disorder from which H. R. H. Prince Leopold suffers from time to time. He is just now recovering from some attacks of hemorrhage.

—Drs J. W. Holland and R. A. Cottrell have been succeeded in the editorial management of the Louisville *Medical News*, by Drs. L. P. Yandell and L. S. McMurtry, who are well known as medical writers.

—At the time of the plague in London, a noted body searcher lived, whose name was Snacks. His business increased so fast that, finding he could not compass it, he offered to any person who should join him in his burdened practice half the profits ; thus those who joined him were said to go with Snacks. Hence, going snacks, or dividing the spoils.—*Morning Herald*, in London *Lancet*, Oct. 6. 1823.

—An Irish woman needing some silk and some tape, sent her husband for them. The silk was shown, but the buyer thought the price too great. The clerk explained that all silk goods were dear, owing to some disease at this time prevalent among the silkworms. The tape was next examined, and the Irishman thought that a little stiff as to price. "And indade, sir," says he, "is there likewoise a dezase a-prevalin' among the tapeworms ?"

—The *Canada Medical and Surgical Journal* is responsible for the following: Not long since a doctor was attending a case of labor. About the time the baby arrived, an older chick of two years had found its way into the sick room, and watched the operation of tying the cord and separating and handing over to the nurse with marked interest. Doctor supposed the little chap was now busy with the nurse, and proceeded to remove the after birth, and just as this was about completed, the little gentleman peeped over the opposite bed-rail and piped out —*more babies, doctor ?*

QUERIES AND REPLIES.

D. N. P., N. C. From the best authorities we have in hand, we are led to say that the dentiphone has turned out a complete failure.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

CLINICAL STUDIES OF INEBRIETY—NOTES ON TREATMENT.

BY T. D. CROTHERS, M.D.,

Superintendent Walnut Lodge, Hartford, Ct.

Notwithstanding all the temperance agitation, seen in both church and society, inebriety is increasing. This is verified by the enormous increase in the consumption of spirits, out of all proportion to the changes of the population, together with the increased manufacture and demand for beers and lighter drinks. Also the increase of pauperism and insanity, and the criminal class, from causes that grow out of inebriety.

The questions of treatment and remedy are fast becoming great national topics.

The nature and character of inebriety, and the means that will practically reach this disorder, are the problems of this age. If inebriety is ever a vice or sin, it is a question for church and State alone, a disorder which must be reached by moral means, and the application of all the machinery of societies, church and State. If this is correct, these means will of necessity lessen and remedy it. Every advance of civilization and morals will diminish or neutralize its development.

The natural history of every case, and all the efforts to reach it from the moral side, furnishes no support to this theory.

If inebriety is a physical disease, the problem is a physiological and psychological one, and its nature and character must be sought for in a knowledge of the physical causes and conditions which break out or develop into this state. The remedies and means of prevention are questions for scientific study, from which the laws and forces governing it can only be understood. The presence of one hundred thousand inebriates in this country cannot be a mere vicious element of human nature, but is really the result of certain physiological and psychological forces, moving in obedience to laws that are fixed and definite.

A history of the different methods of treatment in efforts to cure and prevent inebriety, forms one of the most interesting chapters of psychological literature. Like all other advances of science, the subject of inebriety and its treatment are passing through a formative stage, out of which will emerge the facts and laws which govern its rise and progress, and the means of prevention.

An outline of the different methods of treatment will show the confusion and doubt following this subject at present.

The treatment of inebriety in ancient times varied but little from that of to-day. In the book of Deuteronomy the parents of a rebellious son are commanded to bring him to the elders of the city, and say, "This our son is glutton and drunkard, in order that he should be stoned."

It is clear, from this and other references to drunkenness in the Hebrew civilization, that severe penalties were used to check and prevent such excesses. It was considered a sin to use alcohol beyond a fixed limit of moderation. In ancient Egypt, certain stages of inebriety were called madness, and the victims were confined

in mines and forced to work as slaves. If the offence was repeated, they were held as prisoners and forced to work on the public works, in many cases for a lifetime. Inebriety existed here to a greater or less extent, from the king to the peasant, but was diminished by the eagerness of the monarch to keep up a large force of offenders to do public work.

The physical character of inebriety is clearly outlined in the following sentences, translated from an old papyrus, and evidently written by a temperance man who had violated his pledge.*

"Whereas, it has been told me, that thou hast forsaken books and devoted thyself to pleasure, and that thou goest from tavern to tavern, smelling of beer at the time of evening; if beer gets into a man it overcomes his mind. Thou art like an oar started from its place, which is unmanageable every way; thou art like a shrine without its god; like a house without provisions, whose walls are found shaky. Thou knowest that wine is an abomination; that thou would'st not put liquor into thee. Hast thou forgotten thy resolution?"

Many of the sculptures of both Egypt and Thebes exhibit inebriates in the act of receiving physical treatment from their slaves, such as purgatives and rubbings, or applications to the head and spine. In the Grecian civilization, the question of treatment became more prominent, and decided methods were practiced. Solon enacted laws making inebriety in a governor, ruler, etc., a capital crime.

The senate of Areopagus punished those who were given to drink and convivial company. Plato, in his laws, says, "Shall we lay down a law that boys shall not taste wine at all until they are eighteen years old? Urging that, after that period they might use wine in moderation, and when forty they could indulge freely at the meetings in celebration of the gods. Restrictive legislation existed at this time in varied forms, probably consisting of punishment to those who drank to excess. Pittacus, the lawgiver, instead of allowing inebriety as an excuse for crime, directed that it should be followed by a double punishment. The Greek women at one time used wine so freely that a law was passed forbidding its use, because of the danger of transmitting the tendency to the next generation. Among the Romans, although inebriety prevailed to an alarming extent, yet little effort was made to check it. The Bacchanalians, who held wild revels, in which the worship of Bacchus was celebrated with continuous inebriety, were forbidden by a decree of the Senate to hold any meetings, and were punished for the excesses of drink in which they indulged, but this only lasted a few years. By many of the leading men, inebriety was regarded as a great national sin. The history of several centuries shows that, at intervals, legal restrictions were imposed on inebriates, sometimes very severely. Ulpian, the noted Roman jurist, in the second century of the Christian era, wrote that drunkenness was madness, and that inebriates were sick men, and should be treated as such. In law, they should be considered as largely irresponsible. At one time laws were enacted recognizing the physical character of inebriety, but there are no records which indicate that they were applied practically. The early fathers of the church considered inebriety a sin, and the possession of the devil, only to be cured by fasting, prayer and humiliation. Cases of signal deliverance from this satanic influence are mentioned in a spirit of devout thankfulness and acknowledgment of the grace of God, showing that the influence of church and the power of prayer and faith were used in that early day.

In the thirteenth century the physical character of inebriety was recognized in the lessened punishment for crime in this state. Capital crime in this condition was punished by banishment to an island for a stated number of years. In the next century these laws spread into Germany and France, having been embodied, with various modifications and changes, into the jurisprudence of all nations down to the present time. Thus the theory of the old Roman jurist, that there were certain conditions of inebriety in which the person could not realize the nature of his responsibility, has been recognized from time to time in all the legal efforts to control this disorder. A vague, confused notion of physical disease has prevailed, gathering strength from every careful study of the subject. With but few exceptions, to the church alone was left the whole subject of treatment. Occasionally legal measures would be instituted, but they were seldom carried out any length of time, hence inebriety was one of the sins to which the church devoted its efforts to destroy. A moderate use of spirits was not a sin, but only the gross excesses in which good order and decency were violated. The references of the Bible to drunkards were used in a wide, liberal sense, and marshaled to sustain the theory of vice and wickedness. This has been increased by iteration, from one generation to another, and embodied in essays, sermons and temperance literature, until

*See Tuke on Insanity.

its accuracy is unquestioned; although all scientific and practical acquaintance with the subject furnishes data for the most opposite conclusions.

There are no indications that the punishment of inebriety in the past either cured any one or lessened the prevalence of this disorder.

Severe laws might for a time force the inebriate and his friends to observe secrecy in covering up his condition, but the practical effect of such laws always made the victim more incurable. This treatment by legal means has become more severe and unnatural as the idea of vice and possession of the devil grew in the minds of the public. To-day, where this idea prevails to its fullest extent, the harshest means and the least sympathy are exercised in the treatment. The reform that was conceived and carried out by Pinel, raising the insane to the level of human sympathy, and applying means that would reach down to the wants of every case, has scarcely begun with the inebriate. Although inebriety is the most widely diffused of all maladies, the general methods of treatment are the same to-day as those used in the care of the insane a century ago; outlined in punishment in jails, penal discipline of all kinds, persecution, strict accountability, as those who know fully the nature of their actions and can at all times control themselves. This treatment (as in the care of the insane, long ago) is building up a class of paupers whose presence is a growing menace to all civilization and good government. Some of the difficulties of treatment are found in the obscurity of the disorder and the peculiar delusion of strength and capacity to recover at will. In this way the patient's real condition is concealed from all experts and students of science. The social prejudice against calling a man diseased who can in some instances control himself, and from apparent exercise of the will power abstain from the use of spirits for an indefinite time, is misleading. It conveys the idea that recovery is dependent on the will power alone, when in fact these are but the few exceptions to the rule. To illustrate, take one hundred inebriates who sign the pledge under conditions of much excitement, and all in earnest to get well. Five years later all have relapsed but two or three. These will be men of peculiar nervous organization, who have been profoundly impressed by the act of signing the pledge. The power of the will has been so great as to control the diseased organism, probably aided by many other conditions that are psychical and unknown. Take the same number of cases of malaria; rouse up their minds to the same intensity of thought, and endeavor, and keep this up until the nervous system is fully impressed by it, and without doubt a certain number would recover. Or bring the same number of inebriates under the influence of powerful religious emotions, and introduce the element of expectation of permanent recovery by the means of God's grace, and some cases would be thoroughly cured. The same is seen every day in the faith cures, or places where religious emotions are relied upon almost exclusively to produce cures. Cases of severe organic disease have been apparently checked by this means, and the mind kept buoyed up on faith and expectation, until recovery followed. What these forces are and how they control the organism are unknown; but any inference of their value as means of treatment, to the exclusion of other methods, would be erroneous to the highest degree. The treatment of inebriety is passing through an era of wild empiricism, in which the most extraordinary means and methods are urged as curatives. A mere mention of some of them will be of interest, as illustrating this stage of the history of inebriety. First among them is the "Mind Cure," in which the patient is gradually reduced from the amount of spirits he has been taking, until he goes about with a small bottle in his pocket, educating himself to *touch*, *see* and *handle* it, but *not taste* it. The familiarity of the mind with spirits is supposed to be followed by a disgust and recovery. The will, by this method, is to be built up to control the diseased impulses that demand spirits.

The emetic cure has many followers, and is a system of giving drugs to continually nauseate the patient, and at intervals produce emesis. The irritant or blister treatment, by some unknown process is supposed to remove the cravings for spirit. Blisters of cantharides, mustard and iodine are applied over the spine and stomach. Baths of cold water, both shower and plunge, and profuse sweating, have many advocates. The whisky cure is one that has a wide reputation, but strangely enough there are only one or two instances of its use upon record. The treatment consists of having all food and drink mixed with spirits, until the patient is thoroughly sickened. The method by salt water had some notoriety at one time; consisting of the free use of salt water externally. Whenever the patient felt a desire for spirits, water, both internal and external, was freely applied, and the disease was checked. Tea, coffee, and food

of the richest kinds, have been used to check the impulse to drink, sometimes with success, and generally, they delay the desire for a time. Several instances of this means of treatment are on record, consisting of giving all the tea, coffee and food that a patient can swallow, both after and at time spirits are used. The result is that prostration follows vomiting and general engorgement, and in most cases the derangement of the digestive organs supercedes the acute symptoms of inebriety.

Of six specifics advertised to cure inebriety in this country and England, four were found to contain alcohol in large amounts. The others contained aloes and gentian. Three had some form of opium, two bromide of potassium, and four contained cinchona. One, advertised as Chloride of Gold, contains no gold, but large quantities of zinc. All of little or no value except as general tonics. A half a century ago English and French papers contained advertisements of specifics for insanity, with certificates of cures, which of course were signed by clergymen, who have ever been the first to recognize "short cuts" to health by the means of drugs. Medication has usually been a secondary means of treatment, urged and applied by friends of patients, and when taken by the victim, has been to bring about the ideal state where he could use spirits in moderation. One of the gravest errors in the treatment of inebriety, or application of means for relief, is a journey to Europe. Although there are no records of any cases which recovered by this means, yet it is the constant advice of both physician and friends to inebriates, to go abroad for a change of surroundings, air and scenery, hoping by this means to be restored. Every summer hundreds of this class can be seen on out-going steamers, accompanied by friends, or alone. The discomforts of the voyage, the exciting causes of excesses on the steamer, and the common use of beer and wine, there and throughout Europe, make it almost impossible to abstain.

They are always subject to the usual annoyances and pleasures of travel, with the absence of all regular habits of living and care of their bodies. As a result, they become rapidly more and more chronic. The use of stronger alcohols to excess gives way to large quantities of wine daily, and because the mind does not suffer from stupor, the inference is that much is gained and recovery sure.

Instances are noted of severe spirit drinkers who, in Europe, used wine for a long period of time, and when they returned and began the use of spirits, died suddenly, from some obscure cause following the resumption of stronger liquors. The use of wine may cover up the degenerations that are provoked by stronger liquors; the experience of nearly all cases who return from a health trip to Europe, where the cure of inebriety was the object, is that they are far worse and more broken down in health. All travel which brings new temptations to the victim cannot benefit him, and everything which breaks up the regularity of the organism, followed by a constant strain to adapt itself to the new conditions, must of necessity limit the power of recovery.

Many temperance people are full of hope that the use of beer and wine in place of stronger spirits presages a new era of abstinence and freedom from the evil of spirits. But literally this is only a change in the form of the disorder, to be followed with more certain degeneration, although it may be delayed and concealed from general observation.

The beer and wine drinker are as certainly diseased as the excessive spirit drinker. The former may continue for years without any prominent symptoms, and die at last of some intercurrent disease not recognized, while the latter may have a short-lived course of progressive degeneration to death. Yet both of them follow a march of degeneration that is steady and positive to a fatal termination.

DISGUISED SYPHILIS.

BY T. CURTIS SMITH, M.D.,
Of Aurora, Ind.

Your recent editorial upon this topic was so much to the point, that I think the experiences there related will find their counterpart with many of your readers. How long the human family have been so numerously contaminated with this specific disease is more than I know. I am, by clinical observation, made very sure of one thing, viz., that the ramifications of syphilitic poison are far more varied and extensive than even many medical men will readily admit. Position in society, however exalted and sacred, is no evidence against specific constitutional contamination. I hold in my mind now a large family of parents and children, who will average as high in points of respectability, honor, honesty and religious culture, as any family of a similar number one will find in a day's search. Whether either parent knows or suspects the presence of specific disease in their veins, I cannot say. But sure I am, that one parent died not long since with a disease that, to my mind, had its

origin in a brain lesion that primarily depended on syphilis. The other parent, still living, has a nervous disease—utterly incurable now—the inception and history of which can only be accounted for on the grounds of constitutional syphilis. The children, now quite all grown, and all of whom I have at one time or another treated, have all marked characteristics of inherited syphilis. In every serious attack of any form of disease affecting any of them, there is always a tendency to become chronic in type. If, however, the proper treatment for constitutional syphilis is added or mixed with such other treatment as would be otherwise indicated, they will recover as promptly as any other patients. In this whole family, the disease is so masked that nothing short of a pretty thorough knowledge of constitutional and hereditary syphilis and the whole clinical history of the family, will avail to open any physician's eyes as to their real condition. At my first acquaintance with them I was totally in the dark as to the reason of their slow recoveries from their illness. Once in the realm of real certainty as to the presence of specific disease, I had little more trouble with them than is common with others.

The following case, taken from notes made of it, occurred in practice ten years ago.

Mrs. V., æt. 28, mother of four children, youngest æt. 18 months. I found her pale, anæmic, emaciated, feeble pulse, no appetite, depressed in spirits, and thoroughly broken down. Had been sick for six months, most of the time in bed, during which she had been treated for phthisis pulmonalis, by a fairly capable physician. She and her friends believed she had phthisis, and was incurable. Her respirations were 24 per minute, pulse 120. She had no headache, but considerable vertigo ; was unable to sit up or to lay entirely down ; tongue furred, bitter taste, breath fetid, mucous membrane of pharynx congested and sore ; has frequent, dry, hacking cough; sputa white, frothy and tenacious; voice hoarse and very feeble; respiratory murmur clear, somewhat exaggerated all over both lungs ; resonance clearer and louder than usual, owing, perhaps, to attenuated chest walls; could find no evidence of cavities or of tubercular deposits, though she had twice been the subject of hæmoptysis ; temperature normal. Abdominal viscera quite healthy. Uterus congested; granular cervicitis and profuse muco-purulent leucorrhœa. The post-cervical region presented a few enlarged glands, as did also the inguinal spaces. Sigmund's gland also indurated. Eleven months after her last confinement she had menstruated once, but not after that date. A month later she had slight hæmoptysis, repeated in three weeks again. After that, she had an attack of epistaxis quite regularly, every three to four weeks, the blood continuing to ooze from the nose for three to four days. This hemorrhage nearly always occurred from the left nostril, which I found to be quite closed with a thick, black incrustation. These hemorrhages always increased the already great prostration.

What disease was she laboring under? Evidently not tubercular phthisis. I found no lesion, or set of symptoms to give name to the disease very distinctly or satisfactorily. Reasoning by exclusion, I was only left to strongly suspect that the whole trouble in this case had its origin and continuance in specific contamination. The poison had produced disassimilation through its pernicious influence over the glandular and venous systems, from which resulted a deteriorated condition of blood and enfeebled tissues, giving an outcome of anæmia, emaciation and prostration. This led to deranged menstrual functions, to local congestions and hemorrhages from—perhaps the lungs twice but certainly—the nose, this latter coming from the Schneiderian membrane. These hemorrhages were in the form of vicarious menstruation.

To make the report short, I have only to say, she was put upon anti-syphilitic agents, with ferruginous and vegetable tonics, and some collateral aids. She made a very good recovery and has lived a fairly healthy and useful life since that time, now more than ten years.

If this was not "masked syphilis," what indeed was it? Tonics had been thoroughly tried before I took the case in charge.

A few weeks since a four years' old child was brought to me, with an ugly eruption around the nates. No other difficulty was present, as it would have seemed, by a careless inspection. The report of the case was that it had taken so much medicine, and had so many severe burning applications made, that it seemed useless to try more. The eruption was a year old. A little well directed and quite pleasant anti-syphilitic treatment very promptly relieved the child. Another not dissimilar case, in an adult, was, by a similar plan, promptly relieved. This too had been grossly medicated, and why the real disease in each case had not been promptly detected and relieved, was quite strange indeed, in view of their certain symptomatology.

A young lady was brought to me by her father, some years ago. He was a wealthy and highly

respected farmer. She had a staggering gait, utter inability to look up, *i. e.* raise her head so as to direct the eyes upward, her feet were numb, lower extremities weak and tremulous, the post-cervical muscles were stiff, and turning the head was painful. Any attempt to read resulted in severe pain in the head and general confusion of ideas. The right arm was less sensitive than the left; she had formication everywhere, and constant feeling of depression. She was well preserved, appetite fair, bowels costive, menstruation regular but painful. Her nights were disturbed, often sleepless; had a feeling of bed turning over much of the time. Had I a case of ataxia? A further search showed a few glandular enlargements, some chronic pharyngitis, a history of nasal catarrh, of very frequent attacks of so-called rheumatic pains in the legs, but nothing definite to clear up the case; there was no discovered ear trouble. Her father finally told me she had been through the hands of such and such physicians. I knew them to be capable men. They had named it spinal disease. I placed her on anti-syphilitic treatment, merely on suspicion, viz: mercury and potassium iodide. She made prompt improvement and rapid final recovery. Was this a case of disguised syphilis, inherited? I do not know. If not that, I have no name for it. If a case of ataxia or brain tumor, or spinal meningitis, it could not have recovered so promptly under any treatment.

A young married lady came to me several years ago, pale, anæmic, weak, costive, nervous, considerable insomnia, loss of appetite, and general prostration. Her catamenia were regular; considerable leucorrhœa. Was troubled almost constantly with muscular pains in her extremities, shoulders and breast. No decided symptoms of any particular disease were present. She was barren. With careful directions as to rest and systematic exercise, diet, bathing, etc., I prescribed a tonic course of treatment. No improvement occurred. A month of faithful treatment failed to yield benefit. Repeated search of every organ failed to elicit decided symptoms pointing clearly to any one disease. Nor did her history show specific contamination. A little further knowledge of the husband gave me the key. She was placed on anti-syphilitic agents and promptly regained her health. Was this merely an accidental recovery?

A carpenter, æt. 32, was laboring under what gave all the appearance of being severe intermittent fever. For two weeks I plied him with anti-periodics, in no small doses; yet the chills and fever returned every alternate evening, with unfailing certainty. One night, about 11 P.M., after he had had a very severe paroxyms of apparent ague, I was called to him in great haste, the messenger saying that he was dying, from pain in his head. Visions of a case of extreme cinchonism floated before me as I approached his residence, for I had given him immense doses of quinine. Reaching his bedside, I was not a little surprised to find the pain caused by as typical a syphilitic node on the right frontal prominence as any patient ever had. Suffice it to say that the quinine was replaced with potassium iodide, and followed by very prompt recovery. Not another exacerbation of fever appeared.

I was called in consultation with a physician, to see a child, quite two years old, in a family of the so-called "upper crust." Affluence had furnished every needed comfort. An innocent mother sat watching the crib of her infant. The father—known to have been contaminated—presided with dignity. The child had been long ill and was gradually wasting away. A careful inspection showed the undoubted manifestations of inherited syphilis, which need not be named here. In the consultation the plans of treatment used were set forth by the attendant. No treatment of a specific character was named. The diagnosis of hereditary syphilis was proposed, and after naming the reasons for such an opinion, was assented to by the attendant, and the treatment ordered accordingly. The child made a good recovery. In this case, an able physician knew of the father's contamination, yet if he recognized the heredity of it in this child, he had failed to put his knowledge into practical use.

Only this week, I discharged a case of pleuro-costal neuralgia, regularly periodic in character, and very severe, too, that I treated almost wholly with specific remedies. He took about four or five doses of morphia during the week of treatment, enough cathartics to keep the bowels well open, some slight adjuvant local treatment, but chiefly he took potass. iodid., and hydrargyri biniod. Why such a treatment? Did I know him to be a syphilitic? No. But his habits in general and a few glandular enlargements, carefully sought for, caused me to adopt that plan of treatment. It was successful. So might some other course have proved curative, but I do not believe it would have done so as readily as this did.

A few years ago a young man came to me with temporal neuralgia. Said he could find no relief, except for a while, under morphia. I

found no local cause for his suffering. His teeth were all sound and none of them tender. He was reduced in strength, anæmic, weak, worn out with suffering. His neuralgia came every afternoon. He had no clear manifestations of syphilis, yet I believed him to be contaminated, because Sigmund's gland was enlarged. On this slender testimony alone he was put on a mercurial cathartic, followed by magnesia sulphate, and this was succeeded by the very free use of potassium iodide. He soon recovered thoroughly. He had been on antiperiodics freely without any permanent relief. The specific agents soon afforded the needed comfort.

About a year ago I was called to treat a child of ten years. She was a thin, anæmic child, with poor appetite, costive habit, much continued pain in the right side, in the region of the liver, and extending down to the umbilicus. Also all over the left pleuro-costal region, and continued dull pain in the head. These were always severe in the afternoon, and especially at night. There was no enlargement of the liver, no derangement of digestion, except want of appetite, no sign of lung disease or pleurisy; no evidence of organic brain lesion, no spinal tenderness. She had a severe, hard, dry cough, seemingly produced by a congested condition of the mucous membrane of the pharynx and larynx. The heart beats were normal in sound, but far too frequent. There was no fever; feet and hands cold. What had I here to treat? No very well defined disease, as commonly described or met with, but a case of general debility, anæmia, and nerves crying out for better blood—neuralgia. She was placed, after a cathartic, upon general and ferruginous tonics, generous diet, passive exercise, and as much change of scenery and associations as neighborhood visiting would permit. For three weeks the best tonics and feeding were continued without any observable benefit. I had from the first observed that her teeth showed signs of syphilitic influence, that she had a full pleiades of enlarged post-cervical glands; that the epitrochlear and inguinal glands were adenoid; that there was a shriveled and scurfy appearance of the skin, but her marked debility and anæmia called for the combinations of mineral and vegetable tonics, aside from these specific manifestations. She was now placed on half a grain of hydrarg. proto iodid., three times a day, and iodine tincture over abdomen and left half of chest freely once a day. Tonics continued. The change that took place for the better in the next week was quite surprising to see. Potassium iodide was added then, and the mercury left off for a week. She soon became strong, healthy, vivacious, a rosy hue taking the place of the tawny complexion she had at first. Was this a case of hereditary syphilis? If not, what was it? Two others, a brother and sister, had also some of the ear marks of the disease, and the father was reported to have died of some form of consumption; the mother seemed to be healthy.

Last winter I treated a man, aged about thirty, for pneumonia. He was of good constitution, and soon bid fair to recover, but was left with a severe cough and a hepatized condition of the middle lobe of the right lung. The cough was the result of this and the remaining bronchitis. His use of proper tonics and expectorants availed but little, in ten days, for his relief. On seeing his two-year old boy about this time, it was quite observable that he had many distinct signs of hereditary syphilis. It could not be so without receiving this contamination from one of the parents. The father gave no distinct marks of the disease at that time, but I placed him on potass. iod. freely, and an evening dose of half a grain of hydr. protiod. His recovery from that date was prompt and all that one could desire. Was this recovery simply accidental?

Some months since I was called to see a little child of sixteen months. It had pneumonia, and was very ill. It also had a few clear marks of hereditary syphilis. It was treated for pneumonia without any special reference to this, and made a good and prompt recovery. But the mother was feeble, thin, anæmic, nervous, had sore throat and many muscular pains, especially at night. The clue given by the child led me to a careful investigation of her history. Slowly and by degrees I drew out a syphilitic history, all unsuspected by her, a thing I would scarcely have thought of doing, but for what I had seen of her child in the cradle. She was placed on anti-syphilitic remedies, and made a prompt recovery of all her present ailments. She informed me, when better, that she had taken "so much medicine without being improved, that she had been quite discouraged." Later I treated the husband, and there found unmistakably the first source of this lady's sufferings, and of the child's specific symptoms.

One other case and I will suspend further weariness to your readers. Mr. W., æt. 31, son of a highly respected farmer, had been employed in one of our large cities. His health had so thoroughly broken down, that he "returned to his father's house," bringing a hale and buxom

wife with him. He expected to remain an invalid for life, if country modes of living did not restore him. I was at his father's house six months after his return, on other business, when my attention was called to this invalid and his incurable condition, and I was asked whether I thought it advisable to attempt any further treatment. I found him with tawny skin, fetid breath, severe cough, great pain in the chest walls, very feeble pulse, constant so-called rheumatism of his joints. He was emaciated, dyspeptic, constipated, urine scant, high colored, in short, nothing normal about him. There was no real lung disease, to account for the cough or the pain in the chest. The viscera seemed, for the most part, doing their part as well as they could under the conditions present. He had a few small glandular enlargements, no decided specific marks anywhere, yet his general history and the absence of decided lesions in any organ, led me to suspect syphilis. I said to him. "I do not consider your case hopeless. I think you can be cured." He was placed on anti syphilitic agents, with tonics and good diet. In four weeks he rode twenty miles to see me, and was greatly improved. In two months more he returned to his labor, and has, I believe, so continued ever since, now three years.

Was he a syphilitic? I do not know. If not, the treatment was all wrong. Nor do I know that he had ever had "a chancre." This I do know: every member of the "respectable father's" family, including four sisters and three brothers, showed quite unmistakable marks of laboring under hereditary syphilis, and every one has suffered or do now suffer from this hereditary contamination, if my judgment of their condition is correct. If any one, in view of the multiplied experiences of this kind, by our profession, is disposed to ask "when and where he shall look for syphilitic disease and its ramifications," it certainly would be well for him to change the form of the interrogatory and ask, "where, when, and among whom shall I not look for it?"

I would not have any one infer that every one has it. Some are pure as the morning sun. Nor are mercury and potass. iod. the only remedies for this disease. Far from it. Many others are as valuable in some cases, and more valuable in others, than they are. Great care should be exercised in using mercury. Ptyalism is worse than useless in all cases of syphilis.

It is scarcely necessary to add more cases in this line. No doubt every observant physician has seen scores of them, and an infinite variety of the phases in which this hydra-headed monster arises in practice. It may involve any organ or portion of the system. No tissue is exempt from its baneful influences. There are very few diseases it may not simulate, especially of those of the glandular, muscular and nervous varieties. These may be often relieved without anti-syphilitic remedies, but never so promptly as with them, where the taint is present.

I use the word "*relieved*," because this is as far as we can go. I believe, with Fournier and Hewitt, viz., "a person who is once a syphilitic is always syphilitic, and his very ghost after him will be syphilitic." True, men seem to be cured, and who cannot affect a so-called cure? which only means that the poison is overcome for the time, only to arise in rebellion again at some more favorable season, unless efforts for its complete removal had been very thorough and prolonged. When we remember this fact, and also the salacity of the human race, the want of moral stamina in the millions, and how readily the disease is communicated in venereal indulgences and transmitted to the offspring, there can be little surprise that we find it almost everywhere, or at finding it anywhere among the ranks of society. The wonder sometimes is that physicians so often fail to see it where it is so manifestly and clearly present, though in irregular form.

Shall some say "this report includes many cases where syphilis very probably did not exist, and his general alterative and tonic treatment cured them." I readily grant that this may be so, but I further say that I have for the most part reported cases that were obscurely syphilitic, if so at all, and will also state that in a very large proportion of such cases coming under my hands, they have had other than specific treatment first. This either failed altogether or partially. Then they were placed on anti-syphilitic treatment, and this seemed to effect prompt relief. A large number of such experiences has led me to regard most of these cases as those laboring under specific contamination, the primary lesion having been more or less remote, or not at all known or even suspected by the patient.

Very many cases, clearly syphilitic, yet not known to be so by the patients, could be reported here. But we have preferred to report those cases that were marked and very liable to pass unobserved by even medical men, unless they have had a few eye-openers in this class of practice.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROFESSOR WILLIAM H. DRAPER.

Reported by W. H. Seelye, A.M., M.D.

Hemiplegia.

The examination of the patient by a student, and the reading of the hospital reports, brought out the following facts.

Patient's age is 37. Has had many occupations, but the last was bookkeeping. Has not been much of a drinker, and his habits are good. His father died at the age of 52, from heart disease. His mother was past 70 years of age when she was found dead in bed, one morning. Patient has had typhoid fever, smallpox, measles, scarlatina and all the diseases of children. Has never had much rheumatism, but only a little pain in the joints occasionally. Was never laid up with it.

On awaking, early one morning last June, he felt a peculiar pain in his left hip. He got out of bed but found he could not move the leg, so he began to rub it. There was no sensation below the hip, and it felt to him as if all below this joint was gone. Soon the leg began twitching and jerking up and down, and then it extended to the left side, and finally crept up to his arm and neck. He then lost consciousness for a few moments. The twitching lasted between one and two hours. After the attack there was complete loss of power in the left leg, but nowhere else. During the attack he did not froth at the mouth or bite his tongue. He soon regained the use of his leg, and was well for several months. In September he had a second attack, similar to the first, but he did not lose consciousness. Recovery was not as rapid or complete as after the first one. There was loss of power in the left arm as well as the leg. His third attack was on Sunday morning, October 2d. It was like the others, but it ended with a long continued tonic spasm of the left arm. He has not been able to use his leg since. The next Thursday he gave up business and came to the hospital. On October 18th, at 10.40 P. M., he awoke from sleep with a clonic spasm of the left foot, which extended up the left side and arm, and there was a tremor of the hand. The attack lasted two minutes. It left him weak and nervous. On October 27th he had another attack, with clonic spasms, and violent jerkings of the limbs, which lasted forty-five minutes. The spasms immediately ceased on the introduction of a hypodermic needle into the arm, for the purpose of injecting Magendie's solution of morphia. He has not lost consciousness in any of the attacks since the first. Has had no paralysis of the sphincter muscles of the anus or bladder, no urinary symptoms, no headache, and there was no frothing at the mouth or biting the tongue in any of the attacks.

A brief physical examination showed loss of power in the left leg and arm. The patient remarked that he now felt an attack coming on, but it was only marked by a momentary twitching of the left arm and a slight flushing of the face. There was thought to be a slight murmur with the first sound of the heart. There was noticed a little difference in the strength of the radial pulse on the two sides.

Now, gentlemen, you have heard the history, and seen the physical examination of the patient, such as he can tolerate, and the question arises as to the cause of the trouble. But first, if, as has been suggested, there were a difference in the radial pulse in the two wrists, how might it be accounted for? The most common cause of such a variation, is an abnormality in the origin of the superficialis volæ artery, which may be given off from the radial a little higher up than normal. So that in taking the pulse, the finger may press upon this instead of the radial artery. Or it may be due to a less quantity of blood flowing into the arm, which, for lack of use, is wanting in vitality. Or it may result from an aneurism, or possibly from an embolism higher up in the artery, or from anything causing pressure on the trunk of the vessel. When you find a difference in the radial pulsation, you should always think of all the possible causes of this phenomenon.

We now come to the question of the cause of the hemiplegia in this man. In studying a case of hemiplegia, we must always think of the possible causes of it, which are, briefly, embolism, thrombosis, apoplexy, or a tumor in the brain. Or a temporary spasm of the arteries of the brain causing a disturbance in the circulation, may cause a hemiplegia for the time being. Now how will you proceed to reason from the facts in your possession, as to which of these causes is active here? The proper way is to compare these facts with the peculiar symptoms which are apt to be associated with each cause, in succession. And first, we can exclude a tumor as the cause. For the paralysis resulting from the pressure on the brain of a tumor, is more localized and more persistent than in this case. Most of the attacks here have been followed by only a temporary loss of power, and then a gradual but only partial recovery, which has been less perfect after each attack. We will next look for thrombosis. This is usually the result of a calcification or an endarteritis in the vessels, which causes the formation of a blood clot at some point, which plugs up the vessel. The same result may follow from an endarteritis obliterans. But there is nothing in this man that looks like senility, and his radial arteries show no marks of degeneration. And a thrombosis results in a final obliteration of the artery, and so, from lack of nourishment causes a softening of the brain tissue about it. But here we see no evidences of cerebral softening, and his general health is good. So we exclude thrombosis.

Next comes embolism. This is the plugging of an artery by a clot transferred from some other part, usually from one of the valves of the left heart. The commonest course for such a clot to take is up the left carotid artery, then into the internal carotid, and next into the left middle cerebral or sylvian artery, in which, or its branches, it becomes fixed, and so occludes the artery. Now do the facts in this case point to the probability or improbability of embolism?

Embolism occurs most frequently in youth, and if a hemiplegia occurs at this age it is a strong argument in favor of embolism as the cause, and it is a powerful factor in making the diagnosis. An attack of rheumatism, either in its acute stage or at some time after, is liable to give rise to an endocarditis, which results in the formation of vegetations on the valves of the heart, and this is the origin of an embolus. This man's age is too far advanced to suggest the youthful stage in which we commonly find embolism. There is another fact peculiar to embolic hemiplegia, which will aid in the diagnosis. It is that where you get an obstruction of the cerebral artery from an embolus, you are apt to get other embolic plugs in other regions of the body. For usually there are many vegetations on the cardiac valves, and several of these become detached at the same time, and some go into the carotid artery while others go into more distant vessels. But they are more likely to go into certain organs than to others. Thus a splenic embolism is quite common. And so also with the kidney. But a plug in the renal artery is generally followed by hæmaturia. So it is always important to examine the urine of a child who is suffering from an endocarditis. In embolism of the spleen there is a swelling of that organ, from congestion caused by the interference with the return circulation; for the parts beyond a plug in the splenic artery do become congested and infarctions are apt to follow. When this occurs in the kidney we get hæmaturia. Again, a plug in the brachial artery may occur and cause an absence of the radial pulse in the wrist of that side. As these accidents, which are apt to occur at the same time with a cerebral embolism, are all absent in this case, it is so far an argument against the probability of this being the cause of the hemiplegia in this case.

If we exclude embolism we have left apoplexy. This consists in an extravasation of blood in some portion of the cranial cavity. It may be between the dura mater and the skull, or in the cavity of the arachnoid, or in the subarachnoidean space, or in the substance of the brain itself. The onset of the apoplexy may be either sudden or gradual, and it may or may not be attended with convulsions and loss of consciousness. The symptoms will depend upon the amount, the suddenness and the locality of the extravasation. This man's first attack was accompanied by convulsions and a brief loss of consciousness. He soon recovered, and was quite well for a time; then he had another attack, followed by not so complete a recovery, and then a third, and less complete recovery. So we have to argue that he had three separate hemorrhages before he came to the hospital. But where in the brain could you have three successive hemorrhages, followed by almost complete recovery, in so brief a time?

There is one important point to notice in these cases, gentlemen, and that is, whether there has been any permanent loss of sensation. Where the seats of sensation in the brain are not involved there will be only a temporary disturbance or loss of sensation. But in this man there has been no permanent loss of sensation, but he is rather more sensitive on the paralyzed side than on the other. This indicates that the optic thalamus is probably not involved. You would hardly expect to have any considerable hemorrhage in the corpus striatum, the motor tract, the crura, or the pons, without a permanent paralysis. For a large hemorrhage would be likely to cut off bundles of nerve fibres of considerable size, which would be followed by a permanent paralysis. But yet I think the hemorrhages in this case were in this locality, but were small and only of sufficient size to cause temporary disturbances and paralysis. They may have been either in the cortical substance of the convolutions or in the white substance beneath, and from the decided regional character of the loss of power, it looks as if they had been in the white substance. And this gives weight to the opinion of some, that there are certain localized motor spots in the brain, which, if disturbed, cause a paralysis in certain groups of muscles which they govern. I think that the brief tonic and clonic convulsions from which he frequently suffers now are due to changes going on in and about the clot. For nature sets up inflammatory changes which result in a slow compression and contraction of the clot, and finally it may become almost obliterated. This process of contraction is probably now going on here, and by irritation produces the occasional attacks of which he complains. These attacks were controlled very well for a time by the bromides, but they caused so much constipation that he had to give them up. From the straining, rendered necessary by the constipation, he thinks the loss of power was aggravated. As to the truth of this we cannot say.

Where there has been a large hemorrhage into the brain there is usually a permanent rigidity of the affected muscles, while the changes are going on in and about the clot. But here the limbs are not permanently rigid, but are rather flaccid, and so the clots are probably small. There is a more marked return of power in the leg than in the arm, here. But this is usual, for recovery usually first takes place in the muscles which control extensive movements.

Bright's Disease.

The next patient did not speak English, so a very satisfactory history was not obtained. Patient's age is 25. Born in Denmark; is single; occupation a sailor. Is a moderate drinker. No history of syphilis or rheumatism. Three days ago he began to suffer from headache, pain in the lower extremities and across the lumbar region; cough, with a thick, grayish mucous expectoration, and other febrile symptoms. His bowels have been irregular, but generally constipated. At the time of his admission, on Nov. 8th, his temperature was 101°. Nov. 9th, at 6 A.M., normal. At 12 M., normal. At 4 P.M., 101.4°. Nov. 10th, to-day, at 6 A.M., 103.6°. At present it is 103.6°. He had a chilly sensation at about four o'clock this morning. He has had some slight œdema of the feet, but this has now disappeared. Yesterday his urine contained a little albumen, but no casts. To-day it is free from both. He has passed 48 ounces in 24 hours. It contains no blood, but has a few leucocytes.

You will note, gentlemen, that when he came in he had some fever, and since he came in he has had fever with remissions and exacerbations. He has also had some albuminuria and œdema of the lower extremities, which have pretty well subsided now. These are the clinical facts of importance. He says his last voyage was in a German steamer, from Bremen. He has not been in Africa or South America.

Inspection.—The patient was a large, well built, young man, somewhat fat or fleshy, with light hair and blue eyes, and clear complexion. His face appeared slightly anæmic. The chest and abdomen showed nothing unusual. There was very slight œdema of the ankles.

Palpation.—The abdomen gave no signs of fluid by fluctuation.

Percussion.—The upper margin of liver dullness was on a level with the nipple, and the lower line was at the free border of the ribs, and it extended further to the left than normal. Showing that the liver was much enlarged. The spleen was also found to be very decidedly enlarged. The præcordial dullness was normal, and so also was the pulmonary resonance. Percussion on the back gave the same results.

Auscultation.—There was a prolongation of the first sound of the heart, but this was not very marked. The respiratory sounds were normal.

Now, gentlemen, the symptoms we have elicited are, some œdema of the feet, enlarged liver and spleen, fever, and no affection of the heart or lungs, and slight anæmia. What is the logical sequence of these events? From what is the man suffering? It is probably not acute Bright's disease, for the urine is not diminished. Both in acute parenchymatous nephritis and in congestion of the kidney we get either reduction or complete suppression of the urine, and we are apt to get more or less anasarca, as well as albumen and casts. But none of these conditions are here present.

The œdema might be a sequence of malarial fever. But we have no account of his having been in malarial regions. If we had found that before he came in here he had had regular intermissions or exacerbations we would probably infer that he is suffering from malarial fever. He has the peculiar anæmia and the enlarged spleen and liver of malarial poisoning, and so I think that the primary element was probably a malarial poisoning at some recent time, and this has brought about the congestion of the spleen, liver and kidneys. And now there is a recurrence of the febrile disease; and the watery condition of the blood, together with the feeble action of the heart, have given rise to the œdema.

It may be that he has had, some time ago, more acute symptoms of Bright's disease than he now presents, and so we should be careful to inquire if there has been any reduction in the urine or any œdema, in the past. This extensive anæmia may be the result of a recent acute parenchymatous nephritis. I speak of acute parenchymatous as the most probable form of nephritis in this case, because there is not here the appearance nor the history of chronic Bright's disease. As he cannot speak English we cannot obtain any information as to the former attacks, at present. He will be more carefully examined hereafter.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, October 26th, 1882. The President, Dr. James Tyson, in the chair.

Hypertrophy of the Prostate Gland, Accompanied by Profuse and Fatal Hemorrhage.

Presented by Dr. J. B. Roberts, for Drs. J. M. Adler and Wm. Hunt.

The clinical history furnished by Dr. Adler is as follows: The patient, aged 66 years, of medium size, weighing 150 pounds, of regular habits, had enjoyed good health until within one year past. On a number of occasions during the past year he has had slight hæmaturia. He passed his urine with ease, and only complained of slight perineal pain. On the 12th of September last he arose in the morning, in his usual health, but soon after breakfast he was attacked with sudden, acute pain in the bladder, which he was unable to empty. Dr. Adler saw him in a short time, when the patient complained of great hypogastric pain, and was much prostrated, with a blanched, sallow, cold skin, and a rapid and feeble pulse; a well defined pyriform swelling occupied the hypogastric region, extending upward to the umbilicus. After stimulants and morphia had been given, about one pint of fluid blood was drawn off by the catheter, after which, this instrument becoming blocked, a double one was introduced, by means of which injections of warm water were thrown into the bladder, and another pint of broken down coagula were removed. A solution of alum, 20 grains to the pint, was then introduced into the bladder and allowed to remain. Despite the internal use of ol. terebinth and ol. erigeron, with opium suppositories, the hemorrhage continued, necessitating recourse to the catheter, injections etc., to free the bladder from coagula. Death ensued on the sixth day, from exhaustion induced by the repeated hemorrhages. The diagnosis arrived at by Drs. Hunt and Adler was carcinoma of the neck of the bladder.

Sectio cadaveris.—The autopsy was a partial one, made in the undertaking establishment. Upon incising the hypogastrium, the distended bladder was at once seen, containing nearly a pint of clotted blood. This was removed by the hand, through an opening in the viscus, when Dr. Roberts felt, near the vesical neck, protruding into its interior, a pear-shaped mass, about the size and shape of the adult uterus. This, as the members of the Society saw, was evidently a greatly enlarged middle lobe of the prostate gland, covered by unaltered mucous membrane. The lateral lobes were also enlarged. The mucous lining of the viscus was smooth and congested, presenting at one point two small circular depressions, with cleanly cut edges. Owing to circumstances, no further examination of the body was made.

Dr. Eskridge inquired whether the blood removed from the bladder at the autopsy presented a urinous odor? He had treated recently an interesting case of recurring hæmaturia, supposed to be due to a varicose condition of the veins of the vesical neck. The patient was a man, æt. 77 years, who, five years ago, and at intervals since, had lost considerable blood. The former attacks had yielded readily to ergot, but shortly after the onset of the last one, Dr. Eskridge had found the bladder distended with a large clot, which he had been unable to break down by injections of either alkaline or acid solutions. The secretion of urine was suppressed during the last twenty four hours of the patient's illness, the blood drawn from the bladder presenting no characteristic odor. The man died apparently from uræmia, two or more severe chills preceding death, although no convulsions occurred, and he remained conscious to the last. Unfortunately, no post-mortem examination was obtained.

Dr. Formad thought that the growth resembled rather a sarcoma than carcinoma. He had seen two instances of round-celled sarcoma of the prostate. All growths starting from the epithelia of the genito urinary tract, as well as from the cavity of the uterus, the kidneys and supra-renal bodies, in short, growths of all the organs arising from the middle layer of the blastoderm, microscopically resemble sarcoma, and usually prove to be such, when microscopically examined.

Dr. Tyson said that this specimen possessed a special interest for him, inasmuch as he had had his attention forcibly directed to the differential diagnosis of a simple hypertrophy of the prostate from malignant disease of that organ, by having lately under his care a gentleman, where ergot at first proved of much benefit, but in whose case the catheter was soon demanded. This instrument was used with unusual skill and gentleness by the patient himself, notwithstanding which blood occasionally followed its use. Exceedingly severe pains next developed, radiating from the bladder to the testicles, groins and inner aspects of the thighs. Emaciation soon set in, and he died at the end of 15 months. At the autopsy malignant disease of the prostate was found, involving by infiltration the lateral aspects of the bladder and the neighboring parts, so as to compress the nerves, thus accounting for the radiating pains complained of. He would like to know from Dr. Roberts whether his case presented this symptom of radiating pains, and also the source of the hemorrhage, as the smooth surface of the growth, and the healthy condition of the mucous membrane of the bladder, are such as to excite surprise.

Dr. Roberts, in reply to the various questions propounded, said that, only having made the post-mortem examination, he knew nothing beyond the facts given in the notes read. As to the source of hemorrhage, he would call attention to the two small erosions of the mucous membrane of the bladder as the probable source.

Report of the Committee on Morbid Growths.—The specimen presented by Dr. Roberts, upon microscopic examination, is found to consist of the histological elements composing the prostate gland. There is no evidence of any neoplasm, except a numerical hypertrophy of the structures of the organ. The specimen is a hypertrophic prostate gland.

Caseous Degeneration of the Kidneys.

Presented by Dr. J. B. Roberts, for Dr. Dunmire:—

Owing to Dr. Dunmire not having seen the woman until within a few hours of death, the history is of necessity imperfect. She was a married woman, 39 years old, whose husband is said to have infected her with some form of venereal disease. The husband had been dead for about one year when the patient first came under treatment. There were no evidences of syphilis, so that the supposed venereal affection of the past had been presumably gonorrhœa. When seen, September 14th, 1882, was exceedingly ill. Gave a history of general ill health for the past few years, but dated the present trouble some weeks back, when she had bathed in the surf while menstruating. This was followed by a chill, since when she had steadily grown worse. When Dr. Dunmire saw her she complained of sore throat, difficult deglutition, anorexia, sick stomach, pain in the back, with sharp pain running toward the groin, especially on the right side, tenderness over the abdomen, and frequent, scanty micturition. The pulse was 140, the temperature 103°, and there was profuse leucorrhœa. An unfavorable prognosis was given, which was soon verified by her becoming unconscious and dying six hours later.

Autopsy.—The abdomen alone was allowed to be examined. All organs healthy except kidneys and bladder. The latter contained a little urine and mucus, its walls were much thickened and its lining membrane was congested. The left kidney had little true kidney structure left, but was converted into a group of seven or eight cysts, containing a white, cheesy material, of a moderately firm consistence. The ureter was much dilated and thickened for about three inches from the pelvis of the kidney. The right kidney was normal in outline, but when incised revealed one large cyst, with creamy contents, and also another small cavity containing a few minute calculi. Several of these could be felt through the walls of the normal ureter, thus accounting for the ante-mortem renal colic. The perinephritic structures were unchanged, as well as the capsules of the kidneys, although these latter were perhaps more adherent than normal.

Lymphomatous Tumor of Mediastinum.

Exhibited by Dr. W. S. Little for Dr. G. C. Smith, of Rondout, N. Y.

The history of the patient from whom these specimens were removed is, in brief, as follows: A young man, æt 24 years, had been but a few days under Dr. Smith's care, having come from Boston, where his physician had pronounced him phthisical, and had recommended a sea voyage. During the past few months small, nodular masses had developed in the muscular tissues of the right chest walls, near the median line in front, and also posteriorly. The axillary and supraclavicular glands were involved.

Shortly after Dr. Smith first saw him he developed marked dyspnœa and died suddenly, without any evidences of marked lung disease, except, perhaps, some symptoms of pleuritis. There was apparently mitral disease. Anasarca, especially of the lower extremities, gradually developed.

Sectio cadaveris.—The skin was hard and friable; nodular masses were found disseminated through the muscular tissue of the chest-walls, which had undergone some species of degeneration; the costal cartilages presented evidences of a degeneration similar to that seen in the muscles. On removing the sternum, the subjacent tissues were markedly pigmented, and the anterior mediastinum completely obliterated by a mass of the size and shape of the half of a large lemon, which pressed against the heart. The large bronchi were involved in the growth; otherwise the lungs seemed healthy, and evidences of slight pleurisy were found. The pneumogastric nerves were both involved, chiefly the left, and on further dissection the disease was found to occupy all of the lower part of the posterior mediastinum, involving the contiguous osseous tissues. The nerve involvement explains the sudden death. The diaphragm was also involved in the lower portion of the growth. The four portions of the growth shown to the Society are: 1st, one of the subcutaneous nodules; 2d, a small portion of left lung, near its root; 3d, a portion of the anterior mediastinal growth, with part of trachea, bronchi and aorta; 4th, one-quarter of the tumor, which, involving the diaphragm, projected from the left thoracic wall into the chest cavity.

Dr. Formad inquired whether there were any other evidences of cancer in the remainder of the body.

Dr. Little replied that none were detected.

Dr. Formad then said that he was unaware of any specimen of primary carcinoma of the mediastinum on record, and moved the reference of the specimen to the Committee on Morbid Growths, as it was probably a sarcoma.

Report of the Committee on Morbid Growths.—The mediastinal growths are found, on microscopical examination, to consist of a mass of hypertrophic lymphatic glands, much pigmented. There are also seen adipose and fibrous tissues in a state of active proliferation.

Cirrhosis of Liver in the Stage of Enlargement.

Exhibited by Dr. E. T. Bruen.

T. W., aged 20 years, colored; has worked on a farm since boyhood, and has been much exposed to weather. His habits were temperate; he was free from either syphilitic or malarial taints. Father is still alive; the mother died of phthisis. He was never robust, but had had only one severe illness, viz., typhoid fever, from which he convalesced perfectly, but he readily "took cold." He was first seen by Dr. Bruen at the University Hospital, in January, 1882, when he gave the following history.

Abdomen began to swell two years ago, with neither pain nor tenderness. Was obliged to rise at night, to urinate. The abdominal swelling increased, and the previously regular bowels became constipated. Occasional sharp, shooting pains were felt across the chest when lifting weights or working hard, and also slight, dull pain over liver, lasting for a few moments only. When seen abdomen measured 50 inches. On 19th of January he was tapped, nineteen quarts of fluid being removed, rendering plain a much enlarged liver, covered with smooth, nodular elevations, with the apex beat of the heart displaced upward into fourth interspace. March 18th, five gallons more fluid was removed, after which pleural and bronchial complications arose, which soon subsided. May 6th, paracentesis by capillary needle was resorted to, which was followed by much localized tenderness around the site of the punctures. Symptoms of peritonitis developed next day, which terminated life the same evening. During life, the diagnosis was most difficult and interesting. The enormous size of the liver, the palpable bosselation of its surface giving a sensation like that of crepitating tissue, as though fluid-lymph had been thrown out; and finally his abstemious habits, with absence of either syphilitic or malarial taints, suggested malignant disease. His age, the excessive rarity of primary carcinoma or sarcoma of the liver, with his family history, all negatived this view. He had had some dyspepsia. Enlargement of the liver connected with catarrh of the bile ducts, would have presented symptoms of jaundice, and intermitting temperature, terminating by death from cholesteremia. The case, then, was one of simple cirrhosis.

Sectio cadaveris.—The abdomen contained six gallons of purulent fluid. Both the parietal and visceral peritoneum were covered with a thick coating of inflammatory lymph, tinged with blood, from multiple capillary hemorrhages. The abdominal veins were all replete with blood. The liver weighed nearly 5½ pounds, was of a nutmeg appearance; on section was indurated, and presented a bosselated, nodular appearance. The gall bladder was thickened and contracted about two-thirds in bulk. The bile ducts were normal. The spleen was covered by a pseudo-cartilaginous capsule but was otherwise normal, as were also the stomach, pancreas, intestines, kidneys and supra-renal bodies. The abdominal lymphatic glands were slightly enlarged,

Dr. Seiler remarked that, having seen the case during life it was almost impossible to divest oneself of the idea of malignant disease. He thought that the projections were the unaltered portions of the liver, which had been compressed and squeezed out by the contracting interstitial tissue.

Dr. Bruen remarked upon the obscurity of the etiology.

Dr. Tyson asked Dr. Formad, who had examined the specimen microscopically, whether he considered it to be in the first or second stage of the affection.

Dr. Formad replied that he considered it to be in the commencing second stage, and detailed the microscopical appearances.

Dr. Tyson, after briefly adverting to the causation of cirrhosis, said that his reason for asking Dr. Formad whether he considered that the organ was in the first or second stage of cirrhosis, was, that some few years since an

important insurance case had been argued in our courts, where the defense was set up that the man had not a cirrhosed liver, because it was enlarged. For his part, he had no doubt that a liver could be in the second stage of cirrhosis, and yet be enlarged; there might be enlargement from fatty infiltration, concurrent with interstitial inflammation.

Editorial Department.

Periscope.

Intravenous Injection of Fluid for Hemorrhage.

Dr. C. Edgerton Jennings, in the *Lancet* says:—

On August 20th, at about 3 P.M., M. A. S., a patient of the London Hospital Maternity Charity, pregnant, and nearly at term, fell in the courtyard adjoining her house, suddenly becoming the subject of profuse ante-partum hemorrhage. At 5 P.M. I found her collapsed to a marked extent, lying on a sofa in her bedroom, the pulse barely perceptible, the skin cold and clammy, extreme pallor of the face, an anxious expression of countenance, sighing respiration, and slight jactitation. Blood was flowing from the vagina; the mucous membranes were blanched. Upon examination, I found the os uteri fairly dilated, the right shoulder presenting; the membranes were unruptured, and the edge of the placenta could be felt just within the os uteri posteriorly.

At this critical juncture I remembered the cardinal rules laid down very clearly by Dr. Palfrey in his lectures on Obstetric Medicine, for the management of cases of this description—viz., to arrest hemorrhage, to correct the malpresentation with the least possible shock, and, by cautiously employing stimulants and restoratives freely, to allow the patient to rally and deliver herself spontaneously. A drachm of brandy, with one of water, was injected into the gluteal muscles; the membranes were ruptured, and the left leg brought down into the vagina with considerable ease, owing to the flaccid condition of the parts and the amount of general anæsthesia present. The abdomen was kneaded, the hemorrhage ceasing. To have accelerated delivery at this period would, I think, have proved fatal. Two grains of sclerotic acid, in solution, were injected into the buttock, and the woman was covered up with blankets. I left an assistant steadily kneading the uterus, and returned to the hospital for a transfusion apparatus. Not being able to procure a blood-giver, it was determined to try a saline alcoholic intravenous injection.

I may observe, parenthetically, that great difficulty was experienced in finding a vein, owing to the profound anæmia existing. The patient's right elbow was immersed in hot water, and the cubital triangle thoroughly sponged. These means, added to friction of the part and the adaptation of a turn of a bandage around the arm, were successful in causing the veins to stand out with some prominence; an incision was made over the median basilic, the vein exposed, isolated, and an aneurism-needle armed with a double ligature passed beneath it. The distal ligature was tied, the vein opened, the nozzle of a three-ounce metal syringe, charged with the fluid already prepared, inserted; the proximal ligature tied loosely over the nozzle of the syringe, and the piston pressed slowly home. This was about 6 P.M., the woman being moribund. The syringe was emptied; it was disconnected, refilled and readjusted, the process being continued till sixteen ounces of fluid had been injected. Signs of animation very rapidly appeared—recognition of people present, speech, vision and hearing returned, and complaints of pain in the abdominal region were made. The syringe was withdrawn, the proximal ligature on the vein now tied tightly, the wound closed with the interrupted suture, and a compress and bandage applied. Another grain of sclerotic acid was injected hypodermically, and the case left to nature, delivery occurring at about 7.30 P.M., without any further operative interference whatever.

I may add that the saline alcoholic solution employed in this case consisted of twenty ounces of water at about 100° F., into which was stirred a powder containing exactly the following ingredients: Chloride of sodium, fifty grains; chloride of potassium, three grains; sulphate of soda and carbonate of soda, of each twenty-five grains; phosphate of soda ($Na^3\ Po^4$), two grains. To the fluid thus prepared two drachms of absolute alcohol were added. The subsequent progress of the patient has been most favorable. The highest temperature (Aug. 23d) noted since delivery was 102.4° F.; the wound at the elbow healed kindly, and the woman has proceeded to an uninterrupted convalescence.

I believe I am correct in asserting that transfusion is commonly regarded as a theoretical rather than a practical operation—as one to be performed in the theatre of a hospital, but not in the country village or wayside house. With the view of facilitating the method of intravenous injection, Messrs. Maw, Son, and Thompson, have made for me a small case containing a few feet of elastic tubing, to be used after the principle of a nasal douche or syphon, canulæ of different sizes, a pair of dissecting forceps, with fine points, a scalpel, an aneurism-needle and ligatures, a graduated bottle for alcohol, and room for some saline powders. Here, within very small compass, the accoucheur has the means, with the addition of a jug of hot water, of combating very speedily the effects of alarm-

ing hemorrhage. This is, I submit, a more practical method than the transfusion of blood: here no blood-donor is required, and no risk—it may be urged a trifling risk—to a healthy life incurred.

Unilateral Inguinal and Femoral Hernia.

In the *Lancet*, Dr. J. M. Cotterill says:—

The subject of hernia is one full of interest to the surgeon; and this is mainly due to the fact that not only does considerable difficulty occasionally present itself in making an exact diagnosis, but that we so frequently meet with complications of widely different natures, such as inflammation, adhesions, strangulation, hydrocele, malposition of the testicle, and the like, giving rise in their turn to various symptoms and risks to the patient, and calling for a careful consideration and treatment of each case on its particular merits. In illustration of this statement the following case may be of some interest.

On June 15th, 1882, I was asked to see Mrs. G., aged sixty-four, who was reported to be suffering from severe pain in the abdomen, persistent vomiting, constipation, and other symptoms of intestinal obstruction. The history of the case was, that eight days previously to my seeing the patient vomiting and constipation had set in, and in spite of the adoption of the usual lay treatment in such emergencies, she had grown steadily worse, the abdomen becoming somewhat tense and very painful, and the vomiting after the fifth day of the illness becoming slightly fecal in odor and appearance. Getting alarmed at her condition, she sent for medical advice, and the gentleman who saw her, recognizing her symptoms as those likely to be due to strangulated hernia, and on examination finding an inguinal hernia in her right groin, reduced it without difficulty, and left his patient, as he hoped, in a fair way to recovery. The following day, however, she was considerably worse, and symptoms of collapse so rapidly set in that at noon she was fast sinking, and by the time I reached her house, at two o'clock, she had died.

I had an opportunity of carefully examining the body after death, and found that the hernia, which had been reduced over night, and which was of the direct inguinal variety, had again protruded, owing, no doubt, to the constant vomiting; but it was easily capable of reduction, and it turned out, on inquiry, that the patient had suffered from this reducible hernia for some forty years past. At first I naturally suspected that this hernia had become strangulated, and had been reduced *en bloc*; but on making a more careful examination I discovered a small femoral hernia on the same side of the body, which had escaped previous notice, from its comparatively small size and from the great development of superficial fat over the patient's body. This femoral hernia was about the size of a walnut, tense and irreducible, and there seemed every indication that it had been the cause of death. It seems strange that it had not attracted the notice of the patient, but she had made no complaint of it, and seemed to have been unaware of its presence, referring the pain and other symptoms to the inguinal hernia lying close above it. As no medical advice was sought until two days before death, when, judging from the symptoms, gangrene of the gut and peritonitis had supervened, it is not probable, even if the exact nature of the case had been then recognized and herniotomy performed, that the case would have terminated satisfactorily.

The comparatively rare occurrence of two forms of hernia on one side of the body, and the fact that one of these, apparently the fatal one in this instance, had been overlooked, seem to render this case deserving of record.

The Action of Hot Foot Baths.

The London *Med. Record* says that Dr. Sholkovsky (*Vratsch*, 1882, No. 7) undertook a series of experiments, in order to elucidate the influence of an ordinary hot water foot bath on temperature and circulation in all remote parts of the body. The experiments (as many as 115) were made mostly on quite healthy subjects, and on few weak and anæmic persons, in the period of convalescence from various acute and chronic affections. The duration of bath varied from fifteen to twenty minutes, and the temperature between 107.6° to 114.5° Fahr.; but, as a rule, the author used a fifteen minutes' bath, at the temperature of 108.5° to 110° Fahr. The water reached nearly up to the knee. He arrived at the following conclusions. 1. Under the influence of a hot foot-bath, the temperature in the external auditory meatus gradually rises, reaching its maximum within five minutes after bath. The elevation generally oscillates between 0.1° and 0.3° Reau., but sometimes is as high as 0.5° Reau. 2. The axillary temperature in the vast majority of cases rises also, but less considerably. Its elevation mostly varies between 0.1° and 0.2° Reau., and never goes higher than 0.3° Reau. (one case of 47°). 3. The rectal temperature in the vast majority of cases decreases, reaching its lowest point after bath. The fall is persistent, and generally varies between 0.1° and 0.3°, but sometimes (2 cases of 47°) is equal to 0.4° Reau. 4. Plethysmographic measurements of the upper extremity show that the volume of the limb in the first moments of the bath rather decreases, but then begins gradually to increase, reaching its maximum approximately about the mid-time of the bath, and remaining at the maximal height to the end. After the bath, it begins to decrease very slowly. 5. The measurements of the radial tension, taken by means of Basch's sphygmomanometer, show increase of it during the bath, and the next ten or fifteen minutes. The average increase is equal to 8 millemètres, maximal to 17 millimètres, minimal to 2 millimètres. 6. The observations on the character of the pulse wave (in art. brachialis, studied by means of Rothe's and Knoll's apparatus) show that the latter presents all qualities described by Landois, Moens, Bernard, etc., as typical for a wave under high blood pressure (the more round apex, the appearance of dicrotic indentation, and of so-called elastic elevations nearer to the apex, and so on). 7. The number of pulse beats

generally increases, the maximum of the increase being 24, the minimum 3, the average 5. After the bath, the acceleration of pulse disappears rather rapidly (comparatively with all other phenomena produced by the use of hot foot-bath).

Tardy Development of Scarlatinal Nephritis.

At a meeting of the New York Obstetrical Society (New York *Med. Jour. and Obstet. Rev.*), Dr. J. F. Jenkins narrated the facts of a case as follows, and asked the Society to draw the inferences:—In a well-to-do family in Dobb's Ferry a death occurred, September 6, 1881, from diphtheria following scarlet fever. The family went to the seaside for a month, and in the meantime the house was thoroughly disinfected, regardless of expense, by an officer of the New York Health Board. During the fatal illness the mother remarked to him one day, that on the day previous another of the children had what the servant girl called nettle-rash. It was so trifling, producing no symptoms, that little attention was paid to it. After a month they returned from the seaside to the house, and remained there until January, when they came to New York, and, five months after the fatal illness, and the appearance of the blush on the child's skin, blood corpuscles and a moderate amount of albumen were found in his urine. The physician who saw him believed it to be the result of an attack of scarlet fever, which the child must have had while in the country. Was it likely that a scarlatina dating back over five months was the cause of the appearance of important renal changes?

Dr. John Byrne suggested that the nephritis might have been excited by cold. He had known nephritis to follow scarlet fever after a month, six weeks, or possibly two months, but in the present case, five months having elapsed, he should look for some other cause. Being asked by Dr. Jenkins if he did not think, had the nephritis been present after the thirtieth or sixtieth day from the appearance of the blush, it would have produced positive symptoms before the hundred and fiftieth day, he replied in the affirmative.

Dr. J. E. Janvrin had recently attended cases in which the nephritis made its appearance as late as the fifth or sixth week after the fever, but not later. In one case there was no desquamation until the nephritis developed, when it occurred on the body and extremities; in other respects the scarlatinal attack was normal.

Dr. C. S. Ward could see no reason why Dr. Jenkins' case might not have been one of progressive kidney disease, discovered at a late date.

Phosphorus.

The *Lancet* says that Meyer has been experimenting on the action of phosphorus on frogs and rabbits, employing an emulsion with gum, or a solution in 100 parts of olive oil, the alkaline reaction being carefully neutralized with carbonate of soda. A milligram of phosphorus introduced beneath the skin caused in half an hour a transient increase in the liveliness of the animal's movements. Ten milligrams caused at first excitement, but the animal died in the course of one or two days. No very striking poisonous effects were observed, however, even from the use of larger doses; a diminution of motor power and sensibility came on only after a considerable interval. Once set in, however, the symptoms rapidly increased, and death usually resulted in an hour. No tetanic cramps were observed, and the muscles and nerves after death preserved their normal irritability. The liver, as a rule, presented normal characters, and the heart was distended with blood, slight pulsation continuing in the auricles. Atropine had no influence upon it, but chemical excitants of muscle, salicylate of physostigmin, or camphor, aroused the heart to renewed activity. Further experiments led to the conclusion that phosphorus causes a paralysis of the automatic nerve centres, and later affects the muscular tissue itself. In rabbits, also, no clonic muscular contractions were observed in phosphorus poisoning, but a slow, steady diminution of the blood-pressure, which sank to zero, in consequence of the arrest of the action of the heart. The vaso-motor nerves were not at all affected. Cases of phosphorus poisoning in man have been observed, in which, without any considerable disturbance of the general system or of the central nervous system, death occurs suddenly. Meyer is inclined to regard these as cases of paralysis of the heart, for he succeeded, by introducing phosphorus directly into the circulation, in causing complete paralysis of the heart, before any pathological change had been produced in the heart or liver which could be discovered after death. To exclude the possibility of embolism in these cases, special precautions were taken. An analysis of the blood of rabbits which had been poisoned by phosphorus showed that the amount of carbonic acid which could be extracted had diminished from 50 to 80 per cent., and he thus corroborates the diminution in the process of oxidation in the body and the increased destruction of albuminous bodies.

Writers' Cramp.

The *British Medical Journal* says that Professor Nussbaum, of Munich, has recommended a new method of treatment for this lamentable condition. Considering that, whatever the site of the malady, there is always a spastic contraction of the flexors and adductors, with a weak condition of the extensors and abductors, he set himself to contrive a pen holder that should be directed by the extensors and abductors, instead of the flexors and adductors. This he believes he has accomplished in what he terms a bracelet. This bracelet is a stiff band of gutta percha, oval in shape, about $\frac{1}{8}$th inch thick and $1\frac{1}{2}$ inch broad, having a long diameter of about $3\frac{3}{4}$ inches, and a short of $1\frac{1}{4}$ inch. It is therefore wide enough for all five fingers to be slipped into it, but in using it, the thumb is only just entered, the fourth finger is entered almost as far as it will go, and the little finger is left outside. It is evident that the

bracelet can be held firmly only by expanding the fingers strongly, that is, by the use of the extensors of the first four fingers, and the abductor of the thumb. To this bracelet the pen is screwed, so as to be in contact with the paper when the hand lies on the table. The instrument is made in different sizes, by Stiefenhofer, of Munich. In order to collect a large experience, Professor Nussbaum advertised in the newspaper the gratis treatment of writer's cramp, and had, accordingly, a considerable number of well marked cases. He states most absolutely that every one of these cases at once wrote easily and distinctly with this instrument, not a trace of spasm appearing in any one of them. All expressed themselves as feeling specially comfortable in using it, and some of the patients, after a time, acquired the feeling that they could again write in the ordinary way, without fear of spasm. Professor Nussbaum commends the treatment, therefore, in his preliminary notice of it, for trial by those who have such cases under their care. As we have said, it is extremely simple, and has this very strong recommendation in its favor, that in place of the patient being forbidden to write, he is encouraged to write with the instrument as much as he possibly can, in order thereby to strengthen the antagonists of the muscles liable to the spasmodic contraction.

Veratrum Viride in Puerperal Eclampsia

Dr. N. L. Guice read a paper on this subject at the last meeting of the Mississippi State Medical Association. After reciting several illustrative cases, the author offers the following conclusions.

1. Given hypodermically, in such quantities as will reduce the pulse as low as 60 to 80 beats per minute, the effect upon the spinal nervous centre is such that the convulsive paroxysms are arrested.

2. So long as this effect is maintained by the judicious use of the remedy, the convulsions will be held in abeyance.

3. The convulsions being thus completely within the grasp of the practitioner, time is given, in cases where the labor is progressing, for its safe completion by the natural forces.

4. Where eclampsia has supervened upon gestation, at any period prior to its completion, or at the end of the same, but prior to the inception of labor, the use of the veratrum viride will, by suspending the convulsions, give abundant time for the induction of labor by gentle and safe means, and for its completion by the powers of nature, thus doing away with the necessity for speedy and forcible delivery and the dangers attending that process.

5. Veratrum is easily and safely administered; it does not produce stupor or otherwise interfere with the intelligence of the patient, and thus enables the attendant to form a better idea of the actual state and progress of the disease.

6. It is believed that if the profession will *fairly test* the powers of veratrum in puerperal eclampsia, it will be found to possess marked advantages over all other remedies now in use for that disease.

7. The well-known action of veratrum viride as a *powerful spinal depressant*, coupled with its admirable efficacy in controlling the spasms of puerperal eclampsia, *should lead to a rigid test of its powers against* that painful and fatal disease—*tetanus.*

Amputation of Both Legs Without the Use of Ligatures.

Dr. J. H. Blanks reported the following cases to the last meeting of the Mississippi State Medical Society (*Transactions*):—

Willie D., aged 18, in attempting to get on a locomotive while in motion, received a compound comminuted fracture of the left leg at the lower third, almost severing it, and a crushing injury of the right foot.

He willingly consented to amputation of the left foot, but as there was but very little external laceration of the right, he insisted that an attempt at least be made to save it. This we had but little hope of accomplishing, as the bones were crushed, with evidence of extensive injury to the soft parts and laceration of the blood vessels, but as he would not consent we made the attempt.

He was put under chloroform; then, with the assistance of Drs. Kirkland and Lowry, the left leg was amputated at the junction of the middle and lower thirds; the tourniquet was then relaxed, but no spouting or pulsation at the stump followed, although there was good pulsation at the popliteal space. We waited an hour or more (for hemorrhage); patient was fully from under the chloroform: and then brought flaps together, and applied the usual dressing; left tourniquet in position for another hour, with instructions to nurse should hemorrhage occur, but none occurred. The arteries were not tied and union by first intention, almost, was the result.

Profuse sloughing and offensive suppuration at last convinced my patient that the other foot was lost, but not until septicæmia was well developed.

On the 23d day the right leg was amputated at the point corresponding with the first, with similar results. No vessels ligated; no hemorrhage, and union by first intention.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The extended use of iodoform in surgery is highly commended by Dr. David Prince, in a reprint from the St. Louis *Medical and Surgical Journal.*

——In "A Practical Laboratory Course in Medical Chemistry," Dr. John C. Draper has arranged a number of notes for his students, with intervening blank leaves on which they can be extended from his lectures. The plan is a convenient one (Wm. Wood & Co., New York).

——To the Guiteau literature is to be added "Reflections on Criminal Lunacy, with Remarks on the Case of Guiteau," by Dr. Charles K. Mills (reprint from Trans. Penna. Med. Soc.). He is of opinion that G. was insane, and should not have been hanged. Criminal convicts, he thinks, should be treated in asylums especially for their care.

——In a recent reprint, Dr. C. L. Dana, of New York city, discusses "Some Points in the Physiology of Digestion." His conclusion is that peptones are valuable, but more because they contain much nutriment than because they are very absorbable. They increase metabolism. Pancreatic extracts have not been proved to be of value when given medicinally, and they are probably destroyed in the stomach. They may be of use, he thinks, in partially peptonizing foods before such foods are used.

BOOK NOTICES.

The Physician's Pocket Record and Visiting List. By S. W. Butler, M.D. Revised for 1883. 30 patients, $1.50 ; 60 patients, $2.00.

Of the numerous visiting lists in the market the above has won a large share of patronage from the profession. It has the advantage over all others, that it can be commenced at any period of the year, and will continue useful for twelve months, whereas most others become as useless as an old almanac after the calendar year for which they are designed expires. The "spring clasp" is also highly appreciated, on account of its greater security and convenience.

To those who have not as yet made trial of this list, we recommend that they provide themselves with it for the year 1883. It contains many memoranda and tables of daily usefulness, and compactly and accurately presented.

Questions in Anatomy. By Samuel O. L. Potter, M.D., etc. With 63 illustrations. Philadelphia: P. Blakiston, Son & Co., 1882. Cloth, 8vo, pp. 139. Price $1.00.

This is No. 1 of a projected series of "Quiz-compends," by various authors, designed to help students through their various trials and troubles before they can reach the proud title of M.D. They are an improved form of the ancient "Neill & Smith's Compend," and the various "Aids," and "Vest Pocket Guides," which have, time out of mind, been favorites with students. They are not to be condemned, although they often are. Properly used, they fill a respectable niche; relied upon too exclusively, they are detrimental to sound learning. Of the kind, this is an excellent specimen, as good as any we remember to have examined.

A Guide to Therapeutics and Materia Medica. By Robert Farquharson, M.D. Third American edition. By Frank Woodbury, M.D. Philadelphia: H. C. Lea's Son & Co., 1882. Cloth, 8vo, pp. 526.

The fact that a third edition of Dr. Farquharson's work has been called for in a comparatively short time after the second had been issued, is very satisfactory evidence that it is a book which has solid merit. All will acknowledge this on examining it. The author is a concise, clear writer, and condenses much information in little space. The additions of the American editor are large in amount, and selected with great discrimination.

In his preface to this edition the author notes the comparative lull in therapeutic investigation during the last two years. He does not think that much of value has been added during that time. It is to be hoped that this is but a temporary delay in the onward march of this important branch of our art.

Microscopical Diagnosis. By Chas. H. Stowell, M.D., and Louisa Reed Stowell. Illustrated. Detroit: Geo. S. Davis, 1882. Cloth, pp. 250.

Dr. Stowell begins his volume by a sweeping statement, which we must protest against as untrue. It is this: "The great majority of the medical colleges of this country * * seek to prejudice the students against the scientific investigation of disease." Apparently he refers to the use of the microscope in disease. But certainly he is very far from correct in this statement in any sense, and for the credit of our country and profession we cannot pass it by in silence.

The book is divided into three parts: the first by Dr. Stowell, on the use of the microscope in examining blood, epithelium, muscle, urinary deposits, parasitic disease, tumors, etc. The second part is upon the examination of vegetable fibres, wheat, drugs, etc., and is, we understand, the result of the observations of Mrs. Stowell. The third part is on the mounting of microscopic objects. The text is illustrated with 148 wood-cuts and 47 figures on stone.

The descriptions are clear, and the value of the microscope is set forth with much force and precision. All who are interested in professional progress should familiarize themselves with the practical use of that instrument, and there are few better treatises than this one, to assist them to that end.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D.,
JOSEPH F. EDWARDS, M.D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

PHYSICIANS AND POLITICS.

"It is no wonder," said a lawyer of political prominence to us, some time since, "that you doctors do not carry through the various measures which you all think are necessary for the public health. As a class, particularly as a leading class in learning and social influence, you take less interest in politics than any other. Therefore, it comes that when you want to influence a political body they set but small value on your arguments, because you don't count for much in political life."

This is a fact, and it may be of some interest to enquire why it is.

It is, indeed, more prominently the case in the United States, perhaps, than in any other constitutional country, that physicians shun the political arena. European states count not a few medical men of great distinction in the elective bodies. Professor Virchow, the profound pathologist, has just been returned to the Prussian House of Delegates, by 852 votes against his rival's 153. This rival was Court Chaplain Stœcker, while Virchow is a radical and progressionist. Dr. Lœwe is another Berlin political physician, also recently elected by a sweeping radical majority. In Italy, Professor Mantegezza is no less famous as a medical teacher than as a senator and active worker in politics. The names of Trousseau, Nélaton and other eminent French physicians, were equally familar in the tribune and the forum. Those who have studied in the great medical schools of Paris, Berlin or Vienna, must have noticed the much more active interest in politics among the students than in the colleges of our own land.

This difference is partly attributable to our greater political freedom. Politics is more distinctly a career with us than elsewhere, and unless one pursues it as a career, there seems not much more reason for a man interesting himself in it than in any other business not his own. With us, it is not an appeal to prejudice, so much as a discussion and debate, and hence requires study and preparation.

Another reason, doubtless, is that the reading, the daily pursuits, and the private studies of a physician lead him quite away from the sphere of political life. Most of his patients are women and children, and books of science are grandly indifferent to the struggles of parties.

Still further, as the visits of the physician are not to the house of joy, but to the house of mourning, not to the active worker, but to the bedside of the sick and disabled, courtesy and prudence combine to lead his thoughts and words away from the exciting contests of the day, to narrower and sadder interests. The introduction of political disputes at the bedside is in extremely bad taste.

As a mattter of policy, it is as well for the physician to avoid violent partisanship. He can gain few friends by it, and is sure to lose many. Of course, he may entertain very positive views, and support them at the polls, but their expression at other seasons is of more than doubtful wisdom.

Politics, moreover, cannot be pursued with us

with any success, unless considerable time is devoted to it. But there is certainly no business which suffers more quickly from neglect and irregularity in attention than that of the physician. Hence, he is peculiarly debarred from seeking prominence in it.

In some respects it is to be regretted that these things are so. Had we more physicians among our eminent political leaders, many medical and hygienic reforms would be brought about promptly that must now wait years, decades, or generations; yet we cannot say that we should recommend any young physician to include political distinction among his dreams for the future.

BACTERIA AND CHRONIC DYSENTERY.

In a recent number of the *British Medical Journal*, Dr. James Mackie, of Egypt, contributes an interesting article on Bilharzia Hæmatobia.

It seems that the natives of the interior of Egypt are very frequently troubled with an affection of the rectum, presenting at times many of the characteristics of "piles" or "dysentery," and sometimes they complain of "constant pain and weight in the rectum, with tenesmus."

When closely inquired into, these cases do not present the history of ordinary dysentery or hemorrhoids, but rather resemble a mild form of malignant disease.

If the forefinger is well introduced into the rectum, small, soft, but firm nodules can be felt, often very numerous.

These tumors can be easily twisted off with small, hemorrhoidal forceps, and when placed under the microscope, the blood vessels are found filled with the ova of Bilharzia Hæmatobia.

Now, cannot our own chronic dysentery, that proves oftentimes so obstinate, and in many cases so dangerous to the aged and enfeebled individual, be produced by a similar cause?

Every physician in active practice has more than once had under his care old men suffering from chronic dysentery, upon which drugs would have no avail.

We would suggest to those of our readers who are fond of microscopy, that they would find instruction surely, and might be so fortunate as to make a very valuable discovery in pathology, were they to make a rule of carefully examining the evacuations from these cases. A small shred of rectal mucous membrane might be scraped off with the finger nail and placed beneath the microscope; and no possible chance of obtaining a post-mortem upon one dead of chronic dysentery should be neglected.

Let some one tell us that chronic dysentery is caused by the presence, in the mucous follicles of the rectum, of vegetable parasites, setting up and maintaining an exhaustive inflammation therein.

Let us know the nature of this enemy, and some one will soon discover a means for exterminating it.

The strong resemblance between the symptoms of chronic dysentery and this irritation of the Egyptian bowel, would seem to point to the supposition that the former as well as the latter might be caused by the presence of a parasite.

We are not *bacteria-mad*; but we do see great reason for the suggestion we have made, and feel sure that the search recommended will prove beneficial, in a general way, to the searcher, even though he may fail to make the specific discovery.

PILOCARPIA IN BRIGHT'S DISEASE.

The medical journals for some time past have had more or less to report concerning the use of this comparatively new drug in Bright's disease.

Some apparently wonderfully favorable results have been recorded, while again disastrous failure has been the termination.

That pilocarpia has a definite and permanent place in the therapeutics of Bright's disease, appears to be a well established fact, but the exact nature of its position seems to be but vaguely understood.

Let us start out with the general statement that you cannot *cure* a chronic disease that is dependent upon an absolute alteration of the

tissue of the organ involved; to more specifically illustrate, let us say, that when a certain amount of the tissue of a kidney has undergone waxy, fibroid, or fatty degeneration, no human power or agency can restore it to its original normal composition. Therefore, when such changes have taken place, we must perforce consider the patient afflicted with *chronic degenerative disease* of the kidneys, which, from its very nature, is *incurable.*

But now we are taught by those who have made special study of renal diseases, that this degeneration is oftentimes preceded by an acute disease of the organ, which, passing into the chronic state, becomes incurable.

In the chronic form of the disease, owing to the altered condition of the organ, a part of its ability to perform its duty is lost; in the acute form the same condition obtains.

So, then, we have two conditions of the same disease, the acute and chronic, the one curable, the other not. Now what are the indications for treatment? In the one case you want to cure; in the other you can only palliate.

Remember, that when you offer her favorable conditions, nature always tries to cure, and that the main condition which she imperatively demands is absolute rest of the affected part.

To rest an acutely diseased kidney, you must resort to the well-known compensatory function of the skin. Here comes in the curative action of pilocarpia. If, when you are called upon to treat a case of acute Bright's disease, you will first put the patient to bed and give him sufficient pilocarpia to keep the skin working actively, you will thus rest the kidney and enable nature to return it to its normal condition. This treatment should be continued until all evidences of the disease have disappeared.

In chronic Bright's disease, drugs have but little value, save in emergencies. It is universally admitted that the *hygiene* is of far greater value than the therapeutics of chronic kidney disease. When a man suffering from the chronic disease gives evidence of uræmic poisoning, which indicates that the kidneys have failed to remove a sufficiency of urea, then will the power of pilocarpia prove of great value in forcing the skin to eliminate this deadly poison. In uræmic convulsions hypodermic injections of pilocarpia have been used with most satisfactory results.

Thus, then, we can understand that in the acute disease pilocarpia possesses what may be called curative powers, and that in the chronic form it is a most excellent palliative, and can be relied on in many emergencies. This drug is one of the most active and reliable diaphoretics that we possess, and will therefore prove useful wherever free action of the skin is desired.

CHANGES IN THE SECRETION OF MILK UNDER INFLUENCE OF MEDICINES.

A few numbers ago the Medical and Surgical Reporter mentioned some experiments recently made to determine the influence certain medicines may or may not exert on the composition of the milk, when the drugs are given to the nursing mother. Dr. M. Stumpf has now instituted still more researches in this direction. He made his observations in the Medical Clinical Institute, of Munich, and published his results in the *Deutsch. Archiv f. Klin. Med.* xxx, p. 201.

The investigations were mainly made upon a young goat, the feeding of which was carefully regulated. The influence of iodide of potash, ethylalcohol, lead, salicylic acid, morphia and pilocarpia were employed, and their effect noted concerning quality and quantity of milk; the transfer of these drugs to the milk was also specially examined into. The results were as follows:—

1. Iodide of potash diminishes, salicylic acid augments (probably) the quantity of milk; alcohol, morphia and lead produce no change in the quantity of the milk, while pilocarpia does not enhance the secretion.

2. Salicylic acid augments the percentage of sugar in the milk, alcohol the fatty portion; lead, morphia and pilocarpia leave the milk unchanged in this respect, while iodide of potash disturbs the function of the mammary gland and causes a change of all the parts of the milk.

3. Iodine, united to casein is transferred to

the milk, but the quantity of the drug is subject to individual peculiarities, changing in different animals of the same species. In women the iodine disappears again in the milk as soon as its administration ceases; in herbivorous animals the medicine is found for some time after cessation of introducing the drug into the system, still in the milk.

4. Alcohol is not transferred; of lead, salicylic acid and the other remedies named, only traces were found.

Notes and Comments.

Turpeth Mineral in Croup.

Dr. Fordyce Barker, of New York, places great reliance on this drug in croup. Dr. E. R. Duval, stated, at the last meeting of the Medical Society of the State of Arkansas (*Transactions*), that "For twelve years, after the manner of Dr. B., I have been using the turpeth mineral in the treatment of this disease, and I have, since the adoption of this plan, lost no case of croup.

My treatment has been, immediately upon being called to a case, without stopping to interrogate very closely as to whether I have a croup reflex, catarrhal, or true croup, to administer at once a dose of the agent (from two to five grains, according to age) in honey, syrup, or sugar of milk, and if there is no decided emesis within fifteen minutes, to repeat the dose; and I have never known it to fail to vomit at the second dose; almost immediately a satisfactory response is secured by the first administration. The vomiting is usually free, without effort and without depression. The powder is tasteless, small in bulk, prompt in action, and thorough in effect.

The virtues claimed for it are sedative and revulsive. "It depletes the mucous membrane by an abundant secretion of mucus, which is thrown up; it removes from the larynx, by the forced expiration which it causes, any albuminous or fibrinous exudation which may be there in a diffluent state, and which by remaining may become, subsequently, pseudo-membrane; it acts as a powerful revulsive, and thus diminishes the capillary circulation in the trachea and larynx; and thus it becomes a most effective agent in arresting the inflammatory forces."

If the croup persists after removing the causes of reflex action, then, of course, other therapeutic agencies will need to be essayed; but throughout the attack, be it short or long, whenever the breathing becomes suffocative, from the accumulation of mucus in trachea or larynx, I give the turpeth mineral in the manner and according to the conditions and plan above designated.

The Treatment of Hydrophobia with Curare and with Pilocarpia.

During last month two important contributions to the therapeutics of hydrophobia have been published; one by F. Penzoldt, on its treatment with curare, in No. 3 and 4 of the Berlin *Klin. Wochensch.*, 1882, and one by Denis-Dumont, on its treatment with subcutaneous injections of nitrate of pilocarpia, in the *Gaz. Med.*, No. 24, 1882. We bring the cases as they are reported by Dr. Bernhardt, in No. 32 of the *Cbl. f. d. Med. Wissench.*, 1882, referring our readers, for more details, to the originals.

A boy, aged 11, having been bitten in the lower lip by a dog, became attacked by lyssa on the 11th day. The dog died four days later, but without showing at the post-mortem any characteristic signs. From this may be inferred, that the bite of dogs, even during the period of incubation of hydrophobia in them, or that any bite of any dog has to be considered suspicious. Regarding the period of incubation of this disease in the human being, Penzoldt found that if the bite took place in the hand or arm it was 84 days; in wounds of the face usually 48 days; in the present case remarkably short, 11 days only. Besides the usual well-known prodromic stages Penzoldt considers frequent sneezing as an indication. The case was treated with curare, which, while it acted undoubtedly as a powerful palliative, could not prevent the fatal end.

Dumont's case is as follows: April 16th, of this year, a shepherd, his wife and child, were bitten by a mad dog. The wife died, under symptoms of hydrophobia, May 20th; the boy showed no symptoms whatever. The shepherd was attacked with all the symptoms of hydrophobia (spasms) on May 22; on three successive days, one-sixth of a grain of nitrate of pilocarpia was subcutaneously injected, and the patient totally recovered. Dartigues de Tryol is said to have made similar observations regarding the effect of this remedy.

As a great many remarkable cases, reported in French journals, so this one appears to us somewhat "fishy," and we give it to our readers for what it may be worth, as any contribution to the therapeutics of hydrophobia will be welcome. But we remember that some time

ago very careful observations were made in the celebrated veterinary school of Berlin, regarding the effect of pilocarpia on hydrophobia. It was found to be utterly useless, augmenting, if anything, the disagreeable spasms. It is really a pity, that 99 out of 100 wonderful cures reported in French journals, will nowhere have such effect as in France. *Sapienti sat!*

Partial Resection of the Bladder.

If we are not mistaken, it was Vincent who first wrote an exhaustive treatise on partial resection of the bladder; his work on this subject at least, is well-known. Dr. Ad. Fischer (*Arch. f. Klin. Chir.* xxvii, p. 376), has now made this operation eight times on dogs; five of these cases had a favorable issue. As the details coincide with those of Vincent, we will mention of F's experiments only a few rather important points. He makes use, for the closure of the wound, of a rather peculiar suture, which, to best designate it, might be called an uninterrupted button-suture. He gives, further, the following indications for partial resection of the human bladder with consecutive button-sutures. 1. Injury of the bladder, which cannot possibly heal by first intention. 2. Diverticle of the bladder. 3. Prolapsed bladder-hernia, causing unbearable difficulties, or in case a stone should be present in the prolapsed part. 4. General dilatation of the bladder in a high degree, the cause of which may be removed. 5. Benign and malignant new growths. 6. Diverse kinds of fistulæ of the bladder. 7. Ulcers of the bladder, not to be removed by mechanical treatment, of whatever kind, and where the endoscope shows the threatening rupture.

We think, he might have added another indication; rupture of the organ due to an injury. Here this operation, if performed in time, would undoubtedly find its most important indication, *i. e.*, if the correct diagnosis is possible.

The Radical Cure of Empyema.

As in every cold climate, so in Riga, many cases of pleurisy took place during the years 1878 to 1881. Dr. J. Hampeln had the opportunity of observing a large number of such cases, and he published the reports in the *Ztschr. f. Klin Med.*, iv., 82, p 248. As a result of his great experience he has adopted the following views:—

He prefers in empyema a broad opening of the pleural cavity and partial resection of a rib, with antiseptic after-treatment. To avoid the dangers of this operation he recommends to make first an incision into the skin, and then to puncture the cavity with a flat, bent trocar, constructed by himself. The best place for the operation is near the fourth or fifth costal interspace. Only in case of putrid exudation he makes use of a five per cent. carbolic acid solution to wash out the cavity. Hampeln sums up his experiences as follows:—

A primary or secondary pleurisy of adults, and following some other acute disease, indicates by itself the formation of a thoracic fistula; only in case of very great exudation and of intense dyspnœa, due to the former, and threatening life, provisional puncture may be had recourse to, as a palliative.

2. The earlier, after the acute stage has passed, the thoracic fistula is made, therefore (from two to three weeks), the more favorable will be the issue of the case.

3. In recent empyema the formation of the fistula by puncture is sufficient; in old empyema, however, or when a fistula is in existence already, generally the resection of a rib is necessary.

4. In empyema of children simple puncture should always be tried first, as a curative agent.

5. The most successful after treatment is an antiseptic occlusive bandage.

The Excretion of Strychnia by the Urine.

There has been, perhaps, no fact which has caused so much dispute as the manner in which strychnia is excreted from the body, and if it is chemically decomposed or not. A few months ago, in Gratz, suicide was committed by strychnia. The attending physician reported that he had found the strychnia in the urine. This led to a dispute in the medical journals.

To decide the question, Dr. J. Kratter (*Sep. Abd. Wien. Med. Wchft*, 8, 9, 10, '82; *ref. Deutsch. Medizinal Zeit.*, Aug. 10, '82) has instituted a number of experiments. He gives, what others have usually omitted, all the details of his investigations, and especially the test employed, which was Dragendorff's method. Urine is acidulated with diluted sulphuric acid, in the water bath boiled down one-half, alcohol added; boiled; when cold, filtered, washed with alcohol and the quantity of fluid narrowed down. The acid solution is then shaken with chloroform, the aq. ammonia added, and the same done with the ammoniacal solution. The other process is the usual one. At last, on a watch glass, concentrated sulphuric acid and bichro-

mate of potash form the reactions. Beautiful violet stripes are noted wherever the latter comes in contact with strychnia.

The results of these experiments are as follows: Strychnia, no matter how introduced, is rapidly absorbed and excreted totally unaltered by the urine. This excretion begins already within the first hour after the introduction of the drug into the system, and is ended, latest, within 48 hours, when the last trace of the whole dose can be demonstrated in the urine. The idea of some, that strychnia was deposited in the liver, is not tenable and neither probable. Any accumulative action may simply be explained by the fact that a new irritant acts on the nerve centres, the former irritation of which had not totally ceased as yet, and equilibrium not having been reëstablished before a new dose disturbs it *de novo*.

Misleading Symptoms of Serious Cerebral Disease.

The *British Medical Journal* reports an instructive case that occurred in the London Hospital. A boy, aged 15, diving into the river, struck his head on the bottom. Upon admission he was dull, semi-unconscious, complained only of headache, and seemed to be suffering from slight concussion of the brain. Rest and ice to head was the treatment. In three days he was well enough to go home, but in the evening (before being discharged) was attacked with severe headache, pupils dilated, no paralysis, and speech became difficult. There was now noticed a slight purulent discharge from the ear. These symptoms increased, and the boy, becoming comatose, died the fifth day after admission.

One of the patients in the ward was told by the father of the boy that a discharge had been present before admission, for which he had been under treatment outside, and also that he had previously suffered for some time with headache. This was the first intimation that the boy had been out of health, notwithstanding inquiries made of the friends.

On *post-mortem* examination, the dura mater was found adherent to the brain posteriorly. In the left parietal and temporal region was a blackened spot covering a large abscess-cavity reaching as far as, though not entering, the ventricular space, and containing a considerable quantity of very foul pus. The temporal bone was necrosed, and pus found between that bone and the dura mater.

The coincidence of the injury and the brain-mischief is obviously of much interest, as, supposing the boy had been allowed to go home and then died, it would have been impossible to convince his friends that his death was not due to the injury, and that there had been culpable want of care.

Pathology of Measles.

The celebrated authority on diseases of children, Prof. Henoch, in Berlin, communicates the following instructive case to the Berlin *Klin. Wochenschrift*, 1882, No. 13.

In a girl, aged 4, the eruption of measles during the first two days was normal; but on the third day (the fever continuing uninterruptedly), all over the body, large vesicles (from the size of a hazelnut to that of a silver dollar) made their appearance, filled with a yellowish serum. The eruption of measles assumed a dark red, hemorrhagic form. The vesicles could be seen, not only over the measle-exanthem, but also on parts of the skin otherwise perfectly healthy. After cessation of the vesicular eruption, on the fifth day, the fever abated, but between the sixth and seventh days the temperature ascended again to over 40° C., and a fibrinous pneumonia in the right lower lobe developed itself, which on the eighth day caused the death of the child. A post-mortem examination was not permitted.

Henoch considers the case to have been one of morbilli complicated by pemphigus acutus, and not, as Stemmer (*Cbl.* 1874, p. 575) contended, in a similar case of his own, as the product of a dermatitis morbillosa developed to the highest degree.

We only wish to remark, that the vesicles should have been examined for bacilli. Not long ago we reported in this journal several cases of diabetic persons, where the sudden breaking out of abscesses was found to have been caused by bacteria. We do not doubt that, from some cause or other, micro-organisms of a special type found their entrance into the circulation and gave origin to the pemphigus eruption. We have further, here, again the proof that two diseases may coexist with each other.

Treatment of Writers' Cramp.

A writing teacher, Wolff, in Frankfort, has described a method to cure writers' and piano-players' cramp. His procedure has been tried and greatly praised, especially by Vigouroux. In a late number of the *Deutsch Mediz. Zeit.* (1882, No. 9), Dr. Theo. Schott contends for himself and his brother the priority. As the method is not known, as yet, in our country, we

will describe the same according to Prof. Bernhardt, in the *Centrlbl. f. d. Med. Wiss.*, 1882, No. 33.

It consists in the combined employment of gymnastics and massage. Gymnastics are first practiced by the patient himself. Once or twice daily he has to practice with his fingers, hands and arms, in the order named, and in such a manner that flexions, extensions, ad- and abductions are carried out six to twelve times, with force; the whole procedure occupies about half an hour. Then the same motions are practiced, but each time inhibited by a second person; this has to be done in a very regular, even manner; this part of the method should also be practiced about twice daily. After this, once daily, massage of the muscles and nerves of the arm is practiced; here the work has to be an ascending one, from the periphery toward the centre (to the plexus axillares and cervicalis), and contusions have to be carefully avoided. During the six to eight weeks of this treatment, writing, piano-playing, etc., have to be totally omitted. The cure seems to be certain and lasting, which is very important, as all other methods of treatment have so far been unsuccessful.

Rupture of Liver.

In the *Lancet*, Mr. Sansome reports the case of a man, aged forty-six, who was admitted into the hospital on account of an injury. He was suffering from severe shock, his features being pinched and sallow, surface cold and pulse feeble. There were no marks of violence about the body, and the conjunctivæ were not discolored. The area of hepatic dullness was somewhat extended posteriorly. Hot fomentations were applied, opium administrated internally and milk only ordered. The day after admission he suffered acute pain and nausea, the shock seemed intensified, and stimulants were ordered, but without avail. About 8 P.M. all pain ceased and he expressed himself much better. At 11 P.M. delirium supervened, he rapidly sank, and died at 12.30 A.M. the next morning. The autopsy revealed a large quantity of clear, bloody fluid in the abdomen and on the posterior border of the right lobe of the liver a gaping, jagged wound, three inches in length and one inch in depth at the center. Three inches anterior to this was another wound, two inches long and about one-twelfth of an inch deep. The gall bladder and duct were uninjured. The patient lived thirty-six hours after the receipt of injury.

Treatment of Contracted Finger.

In the *Lancet*, Dr. Edward Bellamy describes the case of a powerful man who some months ago scratched his little finger with a meat-bone. The usual train of symptoms followed, and when he saw him the tip of the little finger was so tightly approximated to the palm that no force could separate it, and strong fibrous bands corresponding with the primary flexures were readily observed. He divided the bands with a von Graefe's iridectomy knife, and extended the fingers forcibly. No good came of this proceeding. He subsequently placed him under an anæsthetic, and carefully and thoroughly extirpated the entire cicatrical tissues, and divided the tendon, with antiseptic precautions. The finger was carefully retained in the straight position, a metal circlet was made for the wrist, and a piece of stout steel clock-spring welded on to it. This steel spring was carried up the dorsum of the finger and suitably attached to it. By its tension it effectually kept the parts on the stretch, and when the wound had healed, passive and active movements, conducted by the patient himself, brought about an excellent result. The finger is as straight as the others, and will be, no doubt, ultimately quite as useful.

Action of Kava.

The natives of the Figi Islands prepare, out of the root of Piper Methisticum, an infusion, which they call *kava*. They prefer the old, dried root, as the fresh root has a disagreeably acrid and bitter taste. The root is worked with water to a pulp and filtered, a cold infusion therefore, and appears then as a turbid, brown fluid, which is refreshing and stimulating, very similar to coffee. It has, besides, a constipating influence, and the over indulgence in it is said to cause enlargement of the liver. Dr. L. Kesteven (*Practitioner*, 1882, p. 199), who has specially investigated this remedy, speaks of a decidedly favorable action of the drug in disturbances of the genito-urinary organs, especially in chronic gonorrhœa, and in chronic cystitis it is said to be almost a specific, and has been used as a remedy in the former disease for many years, with success, by the natives, who rarely, in such cases, have recourse to civilized physicians, but who cure themselves by this drug, which is taken only internally. They live first on a mild diet, take something to purge, mostly Glauber salt, and then, when the acute stage is passed, employ kava. Ten to twelve days is the usual duration of a case of blennorrhœa, with them.

Transient Albuminuria.

As many others, Dr. Kinnicut (*Centralbl. f. d. Med. Wisch.* 33, 1882, ref. by Senator from *Arch. of Med.* 82 vii, 1), has frequently found in apparently perfectly healthy persons of youthful age, and without any disease whatever having preceded it, albumen transiently in the urine. But what is interesting, he noted at the same time a very strong excretion of oxalic and uric acids. He thinks that the cause is, that transiently a large quantity of imperfectly oxidized, nitrogenous material is present in the blood, and that there exists also a vasomotor disturbance, especially in the kidneys, producing the excretion of these products of abnormal digestion. Dilatation of the blood vessels and slowness of the circulation of the blood may also cause a transient disturbance of the epithelium of the glomeruli, a view Heidenhain first expressed. He finds the proof for his assertions in the occasional presence of albuminuria, oxaluria and lithuria ("sediment of urates, lithates), in nervous persons" and under nervous conditions.

How he explains his transient presence of "a large quantity of imperfectly oxidized nitrogenous material," etc., he omits to say; a well-known way of escaping an explanation of something we do not know. But this is the pivotal point of the whole, the *omnium causa* here.

Blue Marks and Pediculi.

The *Lancet* says that some years ago, a French naval surgeon, M. Mowson, pointed out the fact that blue or dusky spots were often found associated with pediculi pubis. Subsequently, M. Duguet succeeded in producing these blue spots by inserting beneath the epidermis a small quantity of a sort of paste made of bruised pediculi. Further observations by M. Mallet, make it probable that the substance producing these spots is contained in the salivary glands. By means of fine forceps, the head of a pediculus was torn off and inserted beneath the epidermis of the fore-arm and near it the rest of the louse was similarly inserted. Next day a blue mark was distinct around the body of the insect, but not around the head. In another experiment a small mass came away from the body of the insect with the head, and in this case the dusky spot developed around the head and not around the body. Further experiments showed that the coloring agent was situated in the body opposite the anterior pair of legs, and at this level it is known that there are two pairs of salivary glands. M. Duguet has pointed out some curious facts regarding the resistance of some persons to the action of the salivary juice and the influence of season on the coloring power of the insect. The blue spots are far more abundant in February, March, and April than in other months.

Correspondence.

A Query About Cowpox.

Ed. Med. and Surg. Reporter:—

Was cowpox communicated to cattle by smallpox virus, or is cowpox a disease as original and peculiar to cattle as smallpox is peculiar to the human family?

"Cowpox is a disease of the cow, arising spontaneously." Dunglison.

This, according to "Webster," would indicate that the disease occurs in cattle without being planted, or inoculated; proof of this is perhaps found in the following:—

Dr. Jenner first caught a glimpse of this great truth (vaccination), which he thoroughly investigated, among the expiring embers of that epizöotic disease (cowpox) which laid waste the herds of this country toward the end of the last century." Aitken.

Cowpox does not occur in the human being except by inoculation, nor does it, when communicated by inoculation, prove fatal to the human family. This latter fact compared, then, with the fact that herds of cattle were laid waste by the disease, it seems to me, would indicate that the soil or system peculiarly adapted to the disease, and in which it may be really at home, is that of the cow and not the human system. Another fact which would indicate that the natural conditions of system for cowpox is not the human system, is the deterioration of the cowpox virus when propagated successively in the human being. And now, if cowpox had once been smallpox, would not bringing the disease in the form of cowpox back into the systems of human beings have a tendency to render the virus, by often repeated vaccinations from person to person, more effective, rather than to deteriorate it. This it seems to me is some evidence that cowpox probably never originated from smallpox.

Smallpox may be communicated to cattle by inoculation though not without some difficulty. It is said instances are on record where the disease was communicated by covering cattle with sheets upon which smallpox patients had lain. Also by cattle grazing where bedding infected with the disease had been spread from time to time, and other instances, and many if not all (except the inoculations) were perhaps genuine cases of cowpox, occurring accidentally in a vicinity where smallpox existed. Smallpox when propagated on the cow, like cowpox when propagated on the human system, loses its virulence. Here is another evidence in favor of cowpox never having originated from smallpox.

The diseases are similar, but I believe not just identical. If they were properly identical, there would be no deterioration by transmitting cowpox to human beings, and vice versa.

Deterioration is the rule where cowpox is propagated on the human system; deterioration is the rule where smallpox is propagated on the cow; no deterioration of virus or disease where cowpox is propagated on the cow. No deterioration where smallpox is propagated on the human being, all things and conditions being equal. Nothwithstanding all these facts, such authorities as Meigs and Pepper say the vaccine disease is an affection produced by the inoculation of the virus of variola, modified by passing through the cow. The proofs which exist as to the truly variolous nature of the vaccine disease in the cow are altogether incontestable, so that we must regard the vaccine disease in the human subject merely as a remarkably modified form of variola.

Now these are excellent authorities on diseases of children, but may not they err? "To err is human." In appearance does not the severely typhoid condition of various diseases closely resemble the specific typhoid fever, and yet they are very different diseases."

"Bartholow," in speaking of vaccination, starts out by saying vaccinia or cowpox is a natural disease occurring in the cow and horse, and possibly some other animals. This means, according to "Webster's" definition of "natural," *not acquired*; he, however, ends the chapter in this wise; the vaccine disease may be produced by inoculation with lymph taken from other cows suffering from the disease, with the lymph of horsepox which is identical with the cowpox, with humanized lymph or retro-vaccination, and by the matter of smallpox or variolation. The latter process has given origin to a good deal of controversy, owing to the difficulty of inoculating cows with the matter of variola, but it has been accomplished a number of times. The results being in all respects the same as ordinary vaccinia, so that the vaccine disease as Jenner, originally maintained, is variola modified by transmission through the system of the cow.

In a few words, it may be said Bartholow, in a chapter of little over a page, starts out by saying the disease cowpox is not acquired, and ends up by saying it is acquired; and now, if such good authorities leave matters in such an unsettled condition, why do they do it? is it because they have no positive proof (though they assert they have)?

If it is possible for smallpox to have previously occurred in the human being, then it is also possible for cowpox to have previously occurred in the cow.

The occurrence of smallpox in the human family (spontaneously) is perhaps settled.

As a suggestion: I offer this that it might interest some of the readers of the REPORTER to have proprieters of vaccine farms state, through your journal, whether their stock of virus is propagated from supposed genuine cases of cowpox, or whether it is knowingly propagated from inoculation of variolous matter communicated to the cow.

Marshalltown, Ia.

NEWS AND MISCELLANY.

Vaccin Charbonneux.

In our issue of November 4th we gave the results of Dr. Klein's experiments with vaccin charbonneux. His observations were reported to M. Pasteur, who, in turn, writes as follows to the *British Medical Journal*:—

"I am much obliged to you for having informed me of the result of Dr. Klein's experiments on *vaccin charbonneux*. These experiments suggest to me the following reflections: The discovery of a means of producing modified virus, and the efficiency of the practical use of such virus in all matters relating to *vaccin charbonneux* have been so thoroughly proved, in various countries, for at least a year, that there is nothing more to be done, in the way of demonstration, to settle the question. It is an accomplished fact that now belongs to science.

"If any experimenter, however competent he may be, and I know that Dr. Klein is very able, fail when he attempts a fresh verification of the question, his duty, in the present condition of science, should be the investigation of the motives by which he is opposed. I have already pointed out that the question of species and race should be taken into consideration. A vaccine which vaccinates rabbits, vaccinates sheep very badly, or to a very small extent. Some breeds of sheep do not tolerate at all, or tolerate very badly, the vaccine which is efficient for another breed. It is advisable that preliminary trials should be made on a small number of individuals, especially if we pass from one country to another, so that we may be assured of the degree of strength of the vaccine: and if it be desired also to find out what is suitable to new species or varieties, mice and guinea-pigs cannot be used for the trial of sheep-vaccine. There are also in the kind of experiment under consideration other sources of possible failure. Thus, I have already pointed out that in one of the experiments undertaken in Italy, the virulent virus employed was septicæmic as well as anthracic. The vaccinated animals died as well as the non-vaccinated subjects.

"Dr. Klein has, as it appears to me, equally failed in proving that *vaccin charbonneux* loses its virulence when cultivated at 42° to 43° Cent., in contact with the air; this is because he has not followed the method pointed out by me, and here also he can only blame himself for his failure. The conclusion of the communication to which I am now replying is prudent to the last degree, for it is certainly most unadvisable to introduce *vaccin charbonneux* into a country where anthrax does not exist."

Professor Pacini on the Claims of Harvey.

A dispute has been lately taking place between England and Italy, as to who really discovered the circulation of the blood; some Italians claiming this honor for Cesalpino, while the English, of course, claimed the discovery for Harvey. The matter seems to be definitely settled at last, by the following letter from the eminent Professor Pacini, of Florence, to Pro-

fessor Johnson, of London, which we take from the *British Medical Journal*:—

"I have read, with the greatest pleasure, your beautiful dissertation (Harveian Oration), respecting the great discovery of the circulation of the blood, which you have been pleased to send me; and, having read it, I am bound to acknowledge that the glory of having demonstrated that discovery by every kind of argument and of fact belongs unquestionably to Harvey. You ought not, however, to wonder that actually the most clamorous of the scientific Italians endeavor to attribute the discovery to Cesalpino. If Cesalpino and Harvey were now living, it is certain that our scientists would consider it a duty to attribute it to Harvey; but both being dead, it is natural that Italian scientists should attempt to claim it for Cesalpino."

Professor Brinton's Tribute to Professor Gross.

In the course of the Introductory Lecture to the Winter Course in the Jefferson Medical College, Professor John H. Brinton said, "It has happened that one who for long years has worn, with singular grace, the robes of professional office, and who for more than a quarter of a century has been alike the pride and ornament of this school, has felt that the time has come when, with every propriety, he may retire from the active duties of his chair, and permit himself that relaxation which advancing years and the sense of duty well performed, justly entitles him to demand.

"Gentlemen, it is not often that a man can so live, prominent for learning, worth and purity, as to forestall the judgment of posterity; it is not often in our profession that contemporary tongues roll up the shout of *αναξ ανδρων*, king of men; it is not often given to living man to pluck the chaplet of immortality and wear it on a mortal brow. Yet all these have been graciously granted to one whom we hold dear.

"All honor, then, to him of whom I speak, whose honors need no roll call; to him, the wise physician, the illustrious surgeon, whose fame is world-wide, and to whose books learned men in every country turn; to him whom royal lips have told that in honoring him Great Britain's august University had honored itself; to him, so long the standard bearer of the American profession; to him, the glory of our school, our own beloved and venerated Gross."

Typhoid Fever in Paris.

Typhoid fever, which may be said to be almost endemic in Paris, has arrived almost to the proportions of an epidemic since the month of June.

The number of deaths from the disease was 161 for the first week in June, and 273 in the last week.

Again, from September 22d to the 28th, there occured 57 deaths, and from September 29th to October 5th, 134 deaths, while in the corresponding weeks of 1881, there occurred respectively 21 and 27 deaths from the disease.

There are at present 2074 cases of typhoid fever in the Paris hospitals; at the Lariboisière hospital alone there are 437 patients. On the two days, October 10th and 11th, 283 cases were admitted into the hospitals. The epidemic has assumed such proportions that most chronic patients have been removed, and barrack hospitals erected at Cochin, St. Louis, etc.

The Cause of the Death of Gen. Anthony Wayne.

The following we take from the *College and Clinical Record*:—

The following scrap of history will be of great interest to medical readers; it is an extract of Henry De Butt's letter announcing the death of General Anthony Wayne, addressed to the Secretary of War, and dated at—

Presque Isle, December 15th, 1796.

"It is with extreme concern I discharge the melancholy duty of announcing to you the death of Major General Anthony Wayne, who, after an exceedingly painful visitation of the gout, expired this morning, between the hours of two and three o'clock. This disorder attacked him about the 17th ult., during a very favorable passage from Detroit hither, where he arrived on the evening of the next day. It by turns affected his feet, knees and hands, with considerable inflammation and a great degree of pain, until about the 3d; when the violence of both beginning to abate inspired flattering hopes of his speedy recovery; but, alas! these were of short duration; for, on the morning of the 3d inst. it appeared that the gout had taken possession of his stomach, where it remained with unconquerable obstinacy and extreme torture, until it put a period to his existence. His remains will be interred to-morrow, within this fort, with military honors."—*Claypoole's American Daily Advertiser December* 31st, 1796.

American Academy of Medicine.

At the recent meeting of the Academy, held in this city, fifty-one new members were elected.

Personal.

—Dr. Philip Leidy has been removed as port physician of Philadelphia, and Dr. Thomas B. Reed has been appointed in his place.

Items.

Errata.—In our issue of Nov. 11, p. 559, line 32 from bottom, for "I have seen used," read "I have *not* used"

—Dr. W. T. Belfield, of Chicago, will deliver the Cartwright course of lectures in New York the coming winter.

—Dr. J. W. Bean, of Cottage Grove, Lane Co., Oregon (graduate of Jefferson Medical College), has been appointed by the Government, physician in charge of the hospital at the Cascades (Cascade Locks, Wash. Co., Oregon).

QUERIES AND REPLIES.

W. S. D., Pa. We have been informed that the constituents of Pierce's Favorite Prescription were ascertained by Hager & Jacobsen, eight or ten years ago, as follows: savine, agaric, cinnamon, cinchona bark, opium, gum arabic, oil of anise, alcohol; quantities were not given.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

TWO INTERESTING CASES OF JUVENILE CONVULSIONS.

Read before the Macon County (Mo.) Medical Society,

BY A. T. LEVICK, M.D.,

Of Woodville, Mo.

On February 14th, 1880, I was called, in a hurry, to see a boy aged 5 years, said to be dying. This boy's history, in brief, is as follows: Was born apparently a healthy child, from healthy parents. When two weeks old, he lay for three weeks in a partially comatose condition, with spasmodic jerks and twitching on one half of his body; he finally got better, but all his life he has been subject to convulsions at times, coming on apparently without cause, and always accompanying any fever he might have. For the last few months he has been in fair health, but has an enlargement of the spleen which seemed to cause him no trouble, and was not treated; the child, although apparently bright, had never talked and had been more or less troubled with worms, which were easily expelled with calomel and santonine. The present attack commenced some time in the night previous to my being called in, the mother being awakened by the child apparently choking and struggling for breath, being black in the face, to use her words, and suffering from a general convulsion, with spasm of the glottis, which made the mother think (who by the way is not overly bright) that the child had a sore throat, to which she directed her domestic remedies, honey and vinegar, pepper tea, etc. The child would have a fit, she said, every five minutes, and would be cold as ice one minute and as hot as fire the next, had a very sick stomach and vomited frequently. This state of affairs continued till between 1 and 2 P.M., when the child's right side (arm, leg, eye and corner of the mouth) was attacked with a jerking, not very fast, but continuous.

I arrived soon after this time, and found the child lying in a cradle, surrounded by several distracted old ladies and the grief stricken mother. The child was lying still and breathing naturally, face rather pale, eyeballs both turned as far in one direction as the recti muscles would allow; pulse was discernible but not countable, from weakness, and quickness; while examining the child, but two or three minutes, there commenced a general spasm of the right side of the body and face; pupils largely dilated. I had the child's head pulled from over the cradle, put my handkerchief over its face, and poured half a gallon of ice water on its head from a slight elevation, but saw no improvement. The patient could not swallow. I had no chloroform or rectal syringe. I then ordered a tub of hot water, put in some mustard, and set patient therein, bathing his body and lower extremities, at the same time keeping ice to his head. The jerking of his right leg kept the water in a perfect commotion; saliva would gather in his throat and mouth, so that we would have to hold his head, that it might run out. After keeping the child in the bath for about five minutes, took him out, wiped him dry, rolled him up in a blanket, but still the spasm kept up. It had then been on perhaps half an hour. I was about at my wit's end; I

could scarcely detect any radial pulse, and then only by bracing cradle against leg with one hand as I searched for pulsation with the other, as the spasm shook every part of the patient; but still there was but one side in convulsion, and that seemed to be internal as well as external, affecting the voluntary as well as the involuntary muscles. The parents had got the child to swallow a good dose of castor oil and turpentine, which acted now copiously; but there was no change. At this stage I took the temperature, for the first time, in both axillæ, and I found it 103 on both sides. I thought now I had the key to the thing; reduce that temperature and you will cure that spasm. So I took a sheet, wrung it out of tepid water, and wrapped up my now naked and still jerking patient. I was still applying cold to his head, and several times would cover his face with a handkerchief and pour on from a quart to half a gallon of ice water. I now cut off his hair and had his scalp continuously rubbed with ice. After patient had been in the wet sheet, which I had frequently sprinkled with cool water, for about ten minutes, I had him taken out, wiped dry, and wrapped up in a blanket. In a few minutes I again took his temperature, which I found reduced two and a half degrees, or to 100½. I had several times tried to give patient a solution of bromide of potassium, but did not know that he swallowed one drop. Still no abatement of the spasm. I then sent a messenger for a syringe and some hydrate of chloral (forgot to send for chloroform). While messenger was gone, and after a continual spasm of one and a half hours, it gradually nearly ceased, but only for about three minutes, then patient could move his eyes, and apparently noticed when called. But in about three minutes I noticed his eyeballs drawn to one side, his mouth begin to draw, his arm and leg to jerk as hard as ever (having never stopped entirely). In this short lull I still kept ice to his head, feet wrapped up in hot cloths, as they were getting cold; pulse at wrist at times not discernible. In a short time patient began to sweat on forehead, a rather cool, clammy sweat; extremities and end of nose cool; it looked as if death was imminent.

When the syringe arrived I took two ounces warm water, 25 grs. bromide potassium, and ten grs. of hydrate of chloral, and injected up the rectum, where it was retained. In about twenty minutes or less patient's jerking partially ceased, that is, all but the fingers and toes; his eyes would roll from side to side and apparently follow a person, but still he made no signs that he could hear when spoken to. I had told the attendants that patient would probably be paralyzed on that side of the body, which proved to be the case. Pinching him or tickling the bottom of his foot was not noticed on the affected side, while on the other side he was extremely sensitive. Pupils would not contract when a strong light was brought in close proximity to them, but kept largely dilated. Pulse was now tolerably strong and about 130, temperature 99½°; patient could not yet swallow, and his mouth had to be wiped free from saliva, to keep him from choking. As I could not stay any longer with the case, I ordered perfect quiet until he could swallow, when he was to receive, every two hours, four powders of calomel, santonine and quinia, with a teaspoonful of a solution of bromide of potassium between each dose. Should he not be able to swallow, and spasm return, to repeat injections of potassium and chloral, ice wrapped in a cloth and constantly applied to head. Left the case at 6.30 P.M.

Feb. 15, 8 A.M., messenger informed me child was still alive, had had no more spasms, was able to swallow, and had slept pretty well during night. As bowels had not moved I ordered a good dose of oil and turpentine. 9 A.M., saw the child, who was asleep; temperature 99°, pulse 130 and weak; pupils, while asleep, contracted, while awake well dilated; could move hand or foot on right side but little; seemed to be easily aroused and to know what was said to him; would take an object with his left hand, and try with his right, but he could not close his fingers. At 10 A.M., two hours after giving oil, gave an enema, which passed at once, with some little fecal matter and one large, round worm. I then left two more powders of calomel, santonine and quinine, to be given every two hours, followed in six hours with oil and turpentine. After taking calomel and santonine, I gave quinine every two hours, with a teaspoonful of a solution of bromide of potassium as needed. Head to be kept cool.

Feb. 16, A.M. Patient apparently doing well; no more spasms, but some trouble in deglutition. Temperature 98½, pulse 120; bowels moved this morning, when he passed several worms. He rested poorly during the night; he can walk a little by being held up; while laying in cradle is continually throwing his left leg over his right. The boy gradually recovered, after taking two more doses of santonine, tonic doses of quinine and bromide, to control restlessness. He was a month before he could use his right arm and leg. Since that time he occasionally has a convulsion, but not so severe or often as

he used to, and is now able to talk a little better. This was the hardest and most protracted case of convulsions I ever saw or read of, and, from its history, it must have been caused first by worms, and secondly by a temperature five degrees above normal.

One other case I have just seen was somewhat similar. June 7th, this year, was called to see a child, six months old, of Mrs. T. R's. It had always been healthy, and was the fattest little baby you ever saw. It lay in its cradle, surrounded by its heartbroken aunts, grandmothers, and all the old ladies for a mile around. I was met at the door by its mother, with the exclamation, in agonized tones, Oh, Doctor, my baby has got the croup and is dying. There was gurgling respiration, from the accumulation of mucus in its throat, and I noticed its left hand and leg jerking. I asked how long it had been jerking that way. They said about two hours. I asked if it had anything like a fit before it commenced jerking on one side only? yes; did it froth at its mouth? yes; was it pretty hot? yes; how was it yesterday? it was all right till evening, when it was funny, and had a little fever; how was it the day before? just about the same, only not so bad. Did you notice it cool any to-day? yes, it was right cold about two hours before this jerking commenced. Pulse was going at the rate of about 200 per minute; could not count it. The child felt rather warm. I put my thermometer in its groin and up it went to 105. This child could yet swallow. I gave it some bromide and about half a drop of tincture aconite. Stripped the child and wrapped it up in a cold, wet cloth, frequently sprinkling it with cool water; took it out in about fifteen minutes, wrapped it up, after drying it, kept cold applications to its head, gave it another dose of bromide, and in about ten minutes spasms ceased; temperature now 103. Put the case on a couple of doses of calomel, followed by quinine, to be given every two hours; the bromide and aconite to be given between each dose, as long as fever was high.

The next morning, June 8th, temperature 100; pulse 120; child drowsy, but could be aroused. Had another one-sided spasm during the night, which was of short duration. The child was perfectly paralyzed on one side, but nursed heartily. Gave two more doses of calomel and continued quinine and bromide, discarding aconite.

Evening, June 9th. Since I had been there the child had several one-sided spasms, and while I was examining it I noticed, first its eyes drawn to the left, then its mouth and cheek, then its left arm and hand, and at last its leg. It would rattle in its throat, and frothy saliva would run from its mouth. This was the kind of spells they said it had been having. This lasted about five minutes. Temperature 99°, pulse 120, regular; respiration 36, regular; face pale; could not use its leg or arm, and would not move its foot by tickling the bottom, but would flinch a little from the prick of a pin. I could not account for these spasms now, from the temperature, but judged there was serous effusion in the right hemisphere of the brain.

I kept child's head cool, bowels open with calomel, and put the case on iodide and bromide of potassium, and an occasional dose of quinine.

In about a week I heard that the child was in apparent good health but still could not use its left side.

June 28th. Child was brought to my office, and upon examination I found its temperature 99, pulse 100; nothing abnormal about the appearance of its head; posterior fontanel closed, anterior considerably opened, but appearing natural; nothing abnormal about its eyes, both pupils being equal, and no strabismus. Child was and had been quite fretful, and at times was said to have some fever; it ate and nursed as hearty as usual. Sensibility on its left side considerably diminished, but would flinch some on the stick of a pin or by tickling the bottom of its foot. But there was nearly a complete loss of mobility in both arm and leg, and it would bear no weight on affected leg; would try to hold an object in its affected hand, but could not flex its fingers. I used the faradic brush with a weak current to its limbs, but could use considerable power before it would appear to notice it. I fancied I could see a little improvement after the use of the battery. I put the case on tonic doses of quinine and strychnine, with bromide and chloral hydrate, as needed, to control restlessness.

Now to what can we attribute the cause of this hemiplegia and former unilateral convulsions? They are but symptoms, what is the disease? It is a lesion of some nerve centre. It may be functional, from some reflex cause, or organic, from clots of blood, effusions, tumors, inflammations, or softening. Any lesion in the continuity of a nerve will produce paralysis; also will any disturbance of the periphery or extremities of nerves; this is generally local in character.

—Prof. Nothnagle has now definitely assumed his duties as Professor of Special Pathology, Therapeutics and the Medical Clinic, at the Vienna University.

PRACTICAL CONCLUSIONS WITH REFERENCE TO ABSCESSES.

BY G. HALSTED BOYLAND, A.M., M.D.,
Of Baltimore, Md.

A pursuance of the subject of suppuration would as naturally lead to that of abscesses, as the physical and chemical course of suppuration in the human body brings about their formation. The definition is drawn when a cavity is filled with or made by the formation of pus, in distinction from suppurative infiltration, which is sharply and technically defined by a collection of pus in a natural, already existing cavity—such as a joint, or the thorax. I am speaking only a word, it is true, with regard to abscesses in general. Nevertheless, it is intended to have more especial reference to those that are developed from an acute inflammation, occurring on the spot where they are seated, as well as to those so-called cold abscesses. The sinking or congestion abscesses which appear at a place further from or nearer to the source of suppuration, not unfrequently, in diseases of the bone, claim really only a technical distinction, belonging essentially to hot abscesses. The same may with equal truth be affirmed of the metastatic abscesses that accompany pyæmia. The subject of abscesses, perhaps, at first glance would seem to be of rather secondary consideration, as belonging to minor surgery, as being quite common and generally unfraught with danger. But a moment's thought cannot fail to convince even a superficial observer, that the study of abscesses is one of the most important and most interesting in all the domain of surgery, and the more so, as they belong to the most frequent of surgical diseases. Their diagnosis (by no means always easy) and their treatment, at times very difficult, merit, therefore, the attention of students and practitioners, both young and advanced, general and special. In order to prosecute the study of abscesses successfully, a knowledge of their anatomical conditions and natural processes is necessary. These may be briefly summarized as follows: 1st. *Seat.* Abscesses can form in all tissues; they have even been observed in blood coagula (plugs of blood). They can form at any depth; although I have oftener found them nearer the surface, than in the depth of an organ. 2d. *Form.* Every abscess has an inclination to a spherical form, and for this reason, that, as a general rule, they are equally, at least on several sides, compressed by tissues of the same consistency. Of course, the form varies at times, now being like a long, deep pocket, and again with several shallow cavities connecting or separated. 3d. The number of the abscesses is sometimes very great in one and the same body; in this case, the formation of abscesses generally rests upon an internal cause. In most cases, however, only one abscess is found, or at most, only a few near each other.

4th. *Direction.* Abscesses have, under all conditions, and no matter where situated, the tendency to enlarge toward the surface of the body. This has its explanation in the greater difficulty which the more tense tissues in the depth offer to its further progress in their direction; nevertheless, further progress and breaking through into a serous sack may be possible. There have been examples of this. The son of I. L. Petit died from the breaking through of an abscess into the cavity of the breast; in such a case the saving of life is no longer to be thought of.

5th. *Construction.* Ordinarily the cavity of the abscess is lined with a characteristic pseudo-membrane, which Delpech accepted as constant in all abscesses, and named, accordingly, membrane pyogénique, abscess membrane. This, however, is not found in very freshly formed abscesses and can also be totally wanting in those that have existed longer, as, for instance, in diffuse phlegmon, and it is of itself understood, that it is not a necessary accompaniment of suppuration, being rather the outcome of a collection of pus. It goes through different modifications, according to the quantity and quality of the pus, more especially as to whether the abscess-cavity communicates with the air or not.

Termination of Abscesses.—Pus being regarded as a diseased formation and foreign body, relatively speaking, cannot remain very long in the human body; causing, like other foreign bodies, a more or less pronounced inflammation in its surroundings. This inflammation induces ulcerative processes, resulting in the abscess breaking through the skin and emptying the pus without. The collection of pus in an abscess can also be removed in another way, although much rarer, namely, by absorption. The abscess membrane is made, by some authors, the organ by whose means the absorption of pus can take place, in a manner harmless to the organism. The fact is that an abscess can empty itself without an opening, and then nothing more remains for us but to accept that the pus has again been taken up into the vascular system.

When resorption of pus takes place in an ab-

scess it is noticed that its volume becomes smaller and its contents thicker. Such a change can go on from one day to another, in the most marked manner. First the pus serum is effused. The pus corpuscles then appear to approach their solution by a transformation of their contents into fat. At least, long before the microscope was used to throw light upon pathological process, it was observed by Dupuytren, and others, that, without doubt, abscesses containing pus, after resorption of the pus-serum, can change themselves into cysts containing fat. This fat has been found to resemble fat-wax, which sometimes develops itself in dead bodies—adipocere.

This fat can likewise later on be resorbed itself; finally, the abscess membrane is pushed together by the surrounding parts and reduced to a fibrous layer, which is not unlike an inscriptio tendineæ. An external and visible impression may remain in the place where the abscess was healed by resorption, but this, by good nutrition, will afterwards fill out with fat. There is, therefore, in this resorption, no fear of pyæmia, for it is a question of resorption of pus serum by secondary formation, in which the pus corpuscles undergo a fatty solution, there being no reception of pus pure and simple into the blood through the porous coats of the vessels. When resorption does not follow, the abscess either empties itself within or without by ulcerative process, or is emptied by mechanical procedure without. The contact with the air, as soon as the latter takes place, causes a reddening of the abscess membrane; it swells, the flow of pus becomes richer, and there undergoes a qualitative change. Besides the already mentioned breaking through of abscesses without or into a serous cavity, there is also a third possibility to notice, viz., the breaking through of an abscess into an intestine covered with a mucous membrane. Such a circumstance presupposes the adhesion or growth of the outer surface of the intestine to the walls of the abscess. Although this is certainly, in general, less favorable than an emptying at the external surface of the body, yet there are cases in which it appears desirable; in abscesses of the iliac fossa, an opening into the colon is a fortunate termination; the case is similar with deep abscesses of the parotid, in which a breaking through externally would cause apprehension as regards a fistula remaining behind, while opening into the cavity of the mouth is not followed by any evil consequences.

On the other hand, breaking through of an abscess into the middle portion of the intestinal canal is very dangerous to life, the more so the nearer the stomach, as the presence of pus interferes with the digestion, and the pus has a long distance to go before it can be removed out of the body. When no other unforeseen evil circumstance occurs, and the cause of suppuration is removed, filling up of the abscess cavity begins with the emptying of pus. This filling up takes place by granulation. When this runs its course normally, cicatrization finishes the physico-pathological process.

Diagnosis.—Samuel Cooper said, most justly, "Nothing is more calculated to make known the sharp and experienced coup d'oeil of a practitioner than the facility with which he recognizes deeply-seated collections of pus; nothing, on the contrary, can so easily shake confidence in him as an error made in this respect."

With heat, swelling, pain, redness and *fluctuation*, our diagnosis, in very many cases, is complete. *Fluctuation* is the decisive point. It is the most certain sign of the presence of pus, being determined by a sensible movement of liquid matter in the tumor (swelling), when struck gently or suddenly compressed for a few seconds. The best way to determine fluctuation is to use both hands, placing one opposite the other on the swelling, and then push, with the open fingers kept close together, the sides of the swelling alternately toward each other. In this manner the contents will often be felt to beat against the sides, and thus fix a diagnosis. Very little difficulty is thus experienced, provided always the abscess can be got at. It is, however, at times not easy, and, indeed, fluctuation may be wanting entirely. This can occur from the consistency and thickness of the parts covering the abscess, from too great a consistency of the pus, and finally, from the abscess being overfilled with pus, and thus producing hard, stiff walls. A strong cathartic, by causing a partial resorption of the pus, often leads us to feel the wanting fluctuation. On [the same grounds fluctuation may fail in ascites, in hydrops of the joints, and in hydrocele. As regards the consistency of pus, with reference to feeling fluctuation, there are organs in which always only very thick pus forms. For this reason, abscesses of the liver, even when situated near the skin, are difficult to diagnose. Broad superficial abscesses, for instance, such as form from a diffuse inflammation of cellular tissue, have no, or at most very indistinct, fluctuation, on account of being spread out in a thin layer.

In spite of all technical rules, the most experienced surgeon cannot sometimes discover fluctuation, while other signs point to the presence of an already completed formation of pus. Here belongs first œdema, the tough, spongy swelling which especially leads us to suspect the beginning of suppuration in the extremities, and which in inflammations of such parts as are surrounded by fast fibrous skins is never absent as soon as they go into suppuration. Further to be noticed are, the etiological conditions, the duration of the inflammation, the texture of the inflamed tissues, the constitution of the patient. The pain, which during the inflammation was spanning or sticking, becomes commonly throbbing, the patient feels often a beat in the abscess isochronic with the beats of the pulse. If fever has already developed itself there are formications or chills.

Among the tumors with which abscesses can be confounded are, particularly, aneurisms. These are tumors with a cavity containing blood, this cavity communicating with an artery. Among them those aneurisms that develop themselves from inner causes (without a wound preceding) are the ones that give rise to such a mistake. To avoid this the following points must be strictly observed: An aneurism forms at first a soft tumor, that in part or entirely disappears upon pressure.

As a distinguishing mark here, the abscess is of harder consistency and less impressionable, the younger it is; in the first stages of its development it is quite impossible to diminish it in the least by pressure. In the further course the relations change, the abscess becomes soft, the aneurism becomes hard, and this change in the consistency in abscesses is most marked on the summit or point, in aneurisms at the base. Arrived here, we can make a correct diagnosis in most cases, for the rhythmic arterial pulsation of an aneurism is absent; we say in most cases, not overlooking the fact that certain abscesses form with a pulsation so like that of an aneurism as to perplex the most experienced. The pulsations, then, that can be felt in both tumors, merit an especial consideration. An abscess often has its seat in the inter-muscular spaces, filled up with connective tissue, in the depth of which the larger arteries run; the abscess can, therefore, by the pulsations of the artery or arteries, rise and fall isochronic with the beats of the heart. But we have here to do with an impulse given to the tumor, which can only be felt distinctly on that side lying nearest the pulsating vessel, and which, by pushing aside, if this can be done, can be at once arrested. On the other hand, an aneurism shows pulsation in its entire circumference, and in form of a widening of the whole tumor isochronic with the pulse and rhythmic. This can be felt whenever and wherever the finger is placed, and is not changed by pushing aside the tumor. The period of existence has a direct influence upon the pulsation in both kinds of tumor. The older the aneurism the less distinct the pulsations, on account of the formation of layers of fibrin on its walls; the older the abscess, contrariwise, the more distinct the pulsations become when situated upon an artery, because, always increasing in size, it continually nears the artery, and its liquid contents extending, are more easily set in motion by the beats of the artery. The conditions become much more complicated when an abscess and an aneurism exist next to each other, or one above the other. The patient may then, only too easily, be the sacrifice to a false diagnosis. The most distinguished authorities of all countries and of all times have made such mistakes. One example, of more modern date, will be enough.* The case was a fluctuating tumor in the axilla, which presented all the appearances of an inflammation of the cellular tissue, in which, however, pulsations were distinctly felt; they were considered as imparted, and the tumor held for an otherwise ordinary abscess. A first incision emptied pus. Then every doubt as to the nature of the tumor seemed dispelled. The bistoury was used a second time, going deeper, in order to widen the incision, at the same instant a powerful stream of bright, red, foaming blood spouted up, and shortly after the patient died. We ought never to proceed to the opening of a tumor about which the slightest doubt remains. The stethoscope will help us to detect the characteristic bruit of an aneurism which is wanting in abscess. The fine exploration trocar, or the acupunture needle are our last resort, and may be introduced into almost any doubtful tumor, without fear or danger.

Treatment.—Ordinarily the emptying of pus is the indication of nature. Only seldom, especially in anti-dyscrasic treatment, is it desirable to favor resorption by cathartics, mercurial ointment, painting with iodine, bandage pressure, etc. The opening of an abscess should not be delayed: 1st. When it is seated in the axilla, near the anus or the urethra, particularly when with fæces or urine pus is mixed. 2d. When the pus is situated deep, under fast fibrous tissues, as for instance, in the hand (also the fingers),

* Bardeleben, Chirurgie, vol. 1, p. 275.

the foot, deep in the thigh, etc. 3d. When, from the beginning on, important functions are interfered with by the situation of the abscess, *e. g.* in abscesses of the pharynx and isthmus faucium. Further, those abscesses should be opened early which threaten danger by their proximity to one of the greater cavities of the body, to the cavity of a joint, to important tendons or bones. The operative treatment of abscess resolves itself into punctures, incisions, setons, cautery and blisters. For most small abscesses a simple puncture with the lancet is sufficient. If there is great reason to fear the entrance of air into the cavity of the abscess, a subcutaneous puncture with a trocar is perhaps better, especially in deep abscesses. The entrance of air into wound cavities has gotten to be a great bugbear, and in the treatment of wounds in general, in which I have had a certain measure of experience, I have never seen any evil effects from it. A simple incision and splitting the pus cavity to about two-thirds of its greatest diameter, is oftenest employed in opening abscesses, and best fulfills the indication in phlegmons, perfect and quick emptying of the pus. The direction and place of the incision are readily determined by the form and situation of the tumor, the long diameter being the one usually chosen. The seton has the advantage of preventing the reclosing of the opening, but leaves an ugly scar. It was for Chassaignac* to improve upon the seton, and owing to him it has become almost obsolete in the treatment of abscesses in general. Our present system of wound drainage is based entirely upon his plan. Instead of the seton, he introduced long tubes of gum, with numerous openings through which it is intended the pus shall flow off, and through which injections can be made, if necessary, to cleanse or irritate a wound surface. The pus does not always flow well through this tube, especially when of a thick, sticky consistency, and in some cases the tube becomes clogged altogether, and the flow is interrupted.

Then free incisions, one on each side of the abscess, should be made at once, in order to obtain unobstructed open drainage. In fact, it were safer to adopt this plan in all swellings that require incision, throughout the whole domain of surgery. During my service on the surgical staff of the French army, in the Franco-Prussian war of 1870--71, we made counter-openings freely. Tubes were used but little. Oftenest not. If the tube is used, it is introduced fastened by a silk thread to an oblique opening (eye) in the point of the stilet. The trocar is first passed through the long diameter of the abscess, and the stilet, with thread and gum tube attached, drawn back, and thus it glides, without difficulty or disturbance of any kind, through the abscess.

Cauterization and blisters merit the lowest place, if they merit a place at all. The former was used, in one case of hot abscess of the cheek that came under my personal observation ; the caustic used was caustic potash, the stick was taken and rubbed over the summit of the abscess until, in a second or two of time, the pus was entirely emptied. It is perhaps a little more painful than puncture or incision, but it leaves a very good, slight and symmetrical scar. This is the only advantage. It is well to employ it for this reason, when the patient is a woman, as the one mentioned was. Hot abscesses are usually single, although I had a case in which there were half a dozen of medium size in different parts of the body, which pointed, broke and healed without treatment, and so rapidly that treatment was really impracticable; they were brought about by too free living on the part of the patient, who had no further trouble as soon as put upon lower diet. The appearance of a small bead of pus on the summit of an abscess is usually regarded as signifying that it is ripe, but do not wait for this if the abscess is red, hot, and fluctuation is distinct. If there is reason to fear that the edges of the incision will close before the cavity of the abscess is entirely filled out, put a wad of charpie in. Emollient cataplasms aid in bringing hot abscesses to ripeness.

In cold or lymph abscesses the contents are, as the name indicates, of a serous or lymphatic character, translucent, with whitish-yellow, caseous flakes, shiny, thready, differing markedly from the pus bonum et laudabile of hot abscesses. Cold abscesses are soft, circumscribed, without pain upon pressure, lying not far under the skin, which retains its normal color. Fluctuation is easily felt. There is no inflammation in the surrounding tissue. The most frequent cause is a dyscrasia. If they grow very large they may, by pressure, then cause pain in the surrounding parts, in which case the skin above them becomes thin, dark red, and finally breaks through in one or more places. The watery contents already described then flow out, and a fistulous ulcer remains, that is very difficult to heal. If such an abscess remains long near a bone the latter suffers with it, becoming carious. It is our

* Traite pratique de la suppuration et du drainage chirugical, Paris.

first duty to treat the dyscrasia, and to think of local treatment only after the general condition of the patient has been improved; we may then try to bring the abscess to resorption, by means of spirituous frictions, painting frequently with tinct. iodine, bandage pressure, cold douche, and, according to Velpeau, blisters. If these do not succeed, and the general health of the patient is better, we may proceed to open a cold abscess, especially if it threatens to break out itself, or threatens a bone by its proximity. It may be opened upon any plan we please, as in this case it is inflammation that we wish to induce, and not to avoid. The same general precautions and rules are applicable in cold as in hot abscess, as regards operative measures. The injection of exciting and irritating medicaments after the opening of the cold abscess with the lancet, is suggested.

Schaack injected red wine or a solution of sublimate or caustic potash; Rust, boiling water. If, after the opening of the abscess, the skin that covers it is very thin, bluish, or near death, it should be cut away with scissors in its entirety, and the wound treated according to remaining indications, generally with stimulating dressings.

Hospital Reports.

UNIVERSITY HOSPITAL.

CLINIC OF JOHN ASHHURST, M.D.

Professor of Clinical Surgery in the University of Pennsylvania.

Reported by Louis J. Lautenbach, M.D

Case 1.—Enlargement of the Prostate.

This man, somewhat beyond middle age, has for some time past noticed that he passes his urine more frequently than he formerly did. He has also noticed that he is required to strain, and that the passage requires a longer time. He has noticed a scalding sensation in the head of the penis, with neuralgic pains in the same region.

The stream which he makes is not propelled with the ordinary degree of force, nor does it have the normal parabolic curve; it comes out slowly and shows no evidence of a propelling force, and falls almost perpendicularly. In stricture of the urethra the stream is narrow, but it is propelled by the ordinary degree of force, and has the ordinary parabolic curve. In enlargement of the prostate there is often no diminution in the size of the stream, but as the propelling force is lost the urine drops vertically.

In order to prove the supposition of enlarged prostate, it is necessary to make a careful examination of the urethra, especially of its prostatic portion, and of the bladder, where we shall probably find a small quantity of residual urine, that is to say, of urine which always remains in a bladder, which cannot be completely emptied. This man has passed water one hour ago, so that if we find urine present in the bladder, its amount will be a moderately fair test of the amount of residual urine. In cases of prostatic obstruction there is usually not much difficulty in introducing an instrument, but sometimes, on account of the curve of the prostatic portion, there is present an obstruction to its introduction. In order to overcome this it is sometimes necessary to use an instrument with a considerable curve. Passing up the catheter we find the prostate enlarged. The amount of enlargement of the middle lobe is not considerable, but the lateral lobes are quite large. Passing the catheter into the bladder, we do not find a very great amount of urine, not as large an amount of residual urine as we frequently see, but it comes out without any force, simply dropping from the end of the catheter. There is enlargement of the prostate without any stricture.

Our patient tells us that he is able to empty his bladder without much trouble. It is very fortunate for him that the obstruction is not of such a form as to interfere completely with the evacuation of urine.

It is very important, when there is much residual urine, that the patient's bladder be completely emptied by catheterization once or twice a day. To relieve the symptoms of which he complains, which I believe to be entirely due to enlargement of the prostate, we will use ergot, which causes contraction of the unstriated muscular fibres, and has been extensively used in enlargement of the prostrate with very good results. If it, however, should occasion bad symptoms, then it will necessarily have to be abandoned, and something else substituted for it.

Case 2. Traumatic Stricture of the Urethra; External Perineal Urethrotomy, without a Guide.

We have in the house a man, whom I carefully examined the day before yesterday, with a bad stricture of the urethra, a traumatic stricture, occasioned by a fall a long time ago. Retention of urine is not present, but there is almost retention; the urine has been constantly dribbling for the last five or six years, gradually becoming worse.

In these cases, before attempting any operation, an examination of the urine must be made, with the view of throwing some light on the condition of the internal organs, and also for the determination of the prognosis. If by this examination evidence of an advanced disease of the kidney is developed, we would not attempt to perform the operation which I propose to do today, because the risks would be too great. If there was advanced disease of the kidney, we would, instead, puncture the urethra behind the stricture, to relieve the bladder, and then trust to being able to pass an instrument at some future time, or allow the patient to remain with a fistula.

The urine has been carefully examined; its specific gravity is 1.020, with a strong alkaline reaction; there is a mere trace of albumen.

The sediment is composed of ammonio-magnesio-phosphate, mucus and pus corpuscles, vesicular epithelium and a few granular casts. From

this examination there is no doubt of the bladder being diseased, and this is aggravated by the ammoniacal condition of the urine, this ammoniacal condition being also increased by the further progress of the cystitis. The two conditions mutually react one on the other. Besides the condition of the bladder, there is undoubtedly some disease of the kidneys; in fact, it would be impossible for him to have stricture so long without its having caused some disease of the kidney. Such examinations of the urine, although of great value, are yet subject to error; that is, a negative result may give rise to the supposition of there being no renal disease. In some forms of kidney disease, however, no albumen or tube-casts are found, and it is just one of these conditions which is often connected with a condition of stricture such as is here present. The interstitial form of suppurative nephritis often gives no evidence of its presence by the urine, and is very apt to be connected with strictures. As we have no further data, however, we must trust to the examination, which leads us to the supposition that there are no marked changes in the kidneys. In this case, therefore, it would not be proper to refuse this patient the best chance which he would have if his kidneys were healthy.

The operation which I consider that it will be necessary to perform here, is that of external urethrotomy; but if I can get an instrument in the urethra to pass the stricture, I will then split the stricture. The latter method, the introduction of an instrument and the splitting of the stricture, is attended with much less danger than the operation by section. There is, in the first place, some risk of hemorrhage in the section method, both primary and secondary bleeding being occasionally met with. Besides the risk of hemorrhage there is the further risk of increasing any existing disease of the kidney, causing uræmia, and there are all the dangers incident to other operations of the pelvis, peritonitis, etc.

We must first make a very careful examination and endeavor to get an instrument into the bladder. The smallest instruments we have are the filiform bougies, which, while of great value, sometimes lead to error, the instrument appearing to have passed the stricture, when in reality its end has turned upon itself. During the examination, keep the patient as warm as you possibly can. First introducing a metallic instrument—a good one to begin with is a No. 15, French scale—into the urethra, we touch the dense cicatricial tissue which constitutes the stricture. This instrument will not pass, and we must go down in the scale, being careful to remember that metallic instruments of very small size may prove very dangerous. Unless skillful, I would not advise you to use such instruments any smaller than a No. 11 or 13 of the French scale, as otherwise you will be apt to produce false passages. In this case there are as yet no false passages, which is favorable. I will now try a No. 7, French scale, which is a dangerous instrument. Although I turn the point in different directions, it does not seem to catch anywhere. Usually the opening in a stricture is not at the centre, but at one side, and if the point of the instrument only presents at the centre, there is but little chance of entering. Using now a No. 6 French scale, with great care, I still fail to enter, and am compelled to resort to the filiform bougies, but with these also am unsuccessful, the end of the instrument turning on itself. Sometimes by giving the end of the bougie a corkscrew turn, it can be made to enter the stricture, but here this also fails.

The only thing that now remains to be done is to perform the operation of external perineal urethrotomy without a guide, the old fashioned "perineal section." Had we been able to get even a filiform bougie through the stricture we could then have used the ingenious instrument suggested by Prof. Van Buren, of New York, and widely popularized by Prof. Gouley. It consists of a catheter, grooved on the back, the end of the groove being bridged over so as to form a tunnel. The tunnel end of the instrument is slipped over the end of the filiform bougie, and thus passed around the bougie, through the stricture, when it can be used either as a catheter or as a staff.

In performing the operation of external urethrotomy you want to get all the light you can. The patient is placed in a lithotomy position and an ordinary staff, passed up to the seat of stricture, is held firmly in the median line by an assistant. The incision for the exposure of the urethra is made in the median line, being careful not to begin further front than necessary, making the incision from an inch and a half to two inches long. The incision is to be carried directly down to the staff. When this has been done you can sometimes make the instrument pass the stricture without further trouble. In order to draw the edges of the wound apart, I am in the habit of using aneurismal needles held by assistants. Feeling now for the groove of the staff, you cut directly down upon it, thus opening the urethra in front of the stricture. Now hunting for the opening in the stricture, a grooved director or a probe is passed in, and the stricture slit up, when immediately a sound can be passed into the bladder; now passing in a catheter at the meatus, the instrument is guided by the grooved director into the bladder. The catheter is left in the urethra for five or six days, that the parts may be moulded about the instrument, as it were, thus facilitating its re-introduction when it is removed. After that time, the catheter is withdrawn and a full-sized sound passed every three or four days. The catheter is secured by means of adhesive strips attached to the skin of the penis itself. Fasten a few strips down along the sides of the penis clasping the catheter, then make these secure by a few circular turns of adhesive plaster about the catheter and a few turns around the penis, being careful not to make the latter to tight.

In this operation we are not obliged to cut any very large vessels, and in consequence, there is usually not much bleeding. The operation, if carefully performed, is not in itself very dangerous, and in the majority of fatal cases death has been caused, not by the operation, but by previously existing visceral disease. It will be necessary for the patient to use the catheter occasionally after he leaves the hospital, in order to keep the urethra dilated, and thus prevent a recurrence of his stricture.

MICHIGAN COLLEGE OF MEDICINE.

CLINIC OF PROF. LA FERTÉ,

Prof. of Anatomy in Michigan College of Medicine.

Mr. A., æt. forty five, whose hand was bruised between two cog wheels.

Gentlemen, I bring this case before you that you may form your own opinion as to whether this wound is healing properly or not.

Suppose we had necrosis of the bone, how would we find it out, or how would we know it? We would know by the sensation we felt on examining it with a probe. We want to know when a wound is doing well, and when it is not doing well; these are points which are very important.

As I said before, we know when there is necrosis, by the grating sensation. Now what causes this grating sensation? It is caused by the bone being denuded of its periosteum; in health the bone is covered by periosteum, but when it is denuded there is necrosis, and you have a rough, uneven surface of bone. We have another disease of the bone, ulceration, in which the surface is not nearly so rough as in necrosis. In ulceration of the bone it is covered with disintegrated bone, somewhat like sand, which is not the case where there is necrosis. In hip joint disease, third stage, where sinuses exist leading to dead bone, you give an injection which is known to possess the property of being capable of removing this material from the surface of the ulcered bone. Now, when you have removed this sandy material from the bone, you have a clean surface and granulation goes on more favorably. In soft parts it is just the same; in soft chancre there is a covering of gray material; to treat the case properly we first dry the ulcer, make use of escharotics, for the removal of this gray material lying over the surface of the ulcer; you now get a clean surface, then stimulate, and granulation goes on nicely. If we had dead bone the edges of the granulation around this wound would be spongy; very characteristic where you have a good deal of dead bone. Where you have a sinus in hip joint disease the margins, according to some pathologists, resemble a hen's anus that is reverted. We will stimulate this a little, it seems to be rather sluggish; you notice these spongy granulations above the integument, sometimes called proud flesh; we will destroy that.

Case 2.—Mr. B., æt. twenty years, who had a deep cut on the ball of the thumb. Gentlemen, here we have a wound, which will heal by granulation or second intention. In a young child with such a wound, we would expect healing by first intention. Some pathologists say, in very young children, the wound can unite by direct adhesion of the surfaces to one another without any inflammation. In first intention there is a certain amount of inflammation, but that inflammation does not run on to suppuration.

The majority of pathologists deny that we can have healing without a certain amount of inflammation, no matter how young the child may be.

In all wounds that heal by granulation, we have a certain amout of serum thrown out; this serum becomes changed into pus; a few hours after the margins of the wound are brought together, you will find along the edges a certain amount of swelling, afterwards the swelling disappears; this swelling is caused by irritation of the blood vessels. The blood vessels become dilated, this dilatation of the vessels produces expansion of the walls, then, as a consequence, they are thinner, and blood cells will be thrown out. After a while this infiltration will be absorbed, when the swelling will disappear and granulation progresses.

These granulations, you will find, are little red dots scattered over the wound; touch one and the patient experiences pain; but whether these bodies have nerves penetrating into them subcutaneously, or simply lying under them, is a disputed point. Blood vessels are freely distributed in these bodies.

From your knowledge of pathology, you will understand that where there is a great deal of swelling we have considerable serum thrown out, and excessive suppuration may take place. As we have commenced with the cold water dressing in this case, we will continue it. Now, what action do we expect to get from the cold water? It will contract the blood vessels, prevent an excessive amount of serum being thrown out; consequently less pus will be formed and granulation take place more rapidly. These stitches we will leave in for four or five days.

Case 3.—Gentlemen, what is the diagnosis of this case? "A swelling, the result of sprain." Now what is a swelling? "Œdema." What causes that œdema? "Effusion." This effusion is characteristic of what? "Inflammation." Now, according to your theory we have inflammation. Is that inflammation in the synovial membrane of the wrist joint or on the dorsum of the hand? "It is on the dorsum of the hand." What other name for inflammation of the cellular tissues? "Cellulitis." Would that cellulitis cause the joints to be stiff? "It would." A filling up of the space between the bones and the integument will prevent the fingers from bending. There is not very much œdema to these fingers, but on the back of the hand is considerable stiffness. What is the stiffness of a joint called? "Ankylosis." For example, in fracture of the leg, there will be stiffness from disuse, inability of the person to move himself. When he tries to move the joint finds firm resistance. What kind of ankylosis do we call that? "Fibrous ankylosis." Sometimes the adhesions are very strong in the joint, when surfaces become knit together so that there is scarcely any motion at all. In all cases of this kind you put the patient under chloroform, all muscular action becomes dormant, and you are able to distinguish between bony and fibrous ankylosis.

Here is a rule to guide you: Always, wherever there is the slightest amount of motion, you may rest assured that the ankylosis is fibrous, no matter how slight the motion; when bony union exists in a joint it is entirely immovable. In bony ankylosis, you may have to chisel out a piece of the bone, in order to bring the limb into a more favorable position. In fibrous ankylosis in the knee joint, for example, you break up the adhesions by force, and follow that up by passive motion every other day, as the case might be. In these cases you will have considerable inflamma-

tion in the joint. You subdue this inflammation by lessening the flow of blood to the part. This is done by pressure on the femoral artery, which will regulate the supply of blood to the part. When you use pressure, watch the patient very closely, for fear of gangrene setting in below the point of pressure. What will we do in this case? Use absorbent remedies; muriate of ammonia, thirty grs. to ℥j; apply a bandage and keep the bandage wet with a solution of thirty grains of the muriate of ammonium to the ounce of water. Also use passive motion, with the hand in an elevated position, to break up the adhesions.

Medical Societies.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, November 2d, 1881, the president, Dr. Edward L. Duer, in the chair.

Dr. Robert P. Harris exhibited twenty-three casts of female bony pelves, illustrating the varities of deformity affecting labor. They were obtained in Paris, by Dr. T. Hewson Bache, for the Museum of the College of Physicians.

Purpura Hemorrhagica.

Dr. Henry Beates related the history of a child, healthy for the first four months of its life, at which age it was attacked by thrush; ten days later an ecchymosis of purpuric character appeared on one leg, and a few days later spots of the same character appeared over the body; on the fifth day the stools were tarry, showing intestinal hemorrhage; a bronchial secretion was also stained with blood; on the seventh day a hemorrhage started from an abraded spot on the perineum; various local styptics were applied to this spot without result, until a red hot needle was used as a cautery; on the tenth day a hemorrhage occurred from the canthus of one eye, and on the fifteenth day the child died, from exhaustion. At the autopsy the internal organs were found quite exsanguine.

Bursting Pelvic Cyst.

The patient had been for some time in poor health. Nine months ago she observed a tumor in the right iliac region. On one occasion, after slight exertion, she felt something give way; this was followed by intense pain and collapse; she recovered, and has had no return of the tumor.

Hemorrhagic Diathesis.

Dr. Wm. Saveny related the history of a boy, five years of age, who had fallen and received a slight wound of the scalp from a nail sticking out of a post; it was a mere scratch, and did not need a stitch to hold it together, but it bled profusely; all sorts of domestic remedies, including cobweb, had been tried, without avail. The doctor finally succeeded with lint, wet with Monsel's solution, and continued firm pressure. A few days later the same boy fell off of one step on to the floor, there was no external wound nor loss of blood, but the side of the face was enormously swelled, from hemorrhage into the tissues. A course of iron and tonics has improved the boy's appearance, but he is still pale.

Dr. Harris inquired if there was any history of hæmophilia in the family? Had the boy large knee-joints? There is a hemorrhagic diathesis entirely distinct from true hæmophilia. The latter is rare in cities, but is more frequent in the country. The descent is through the females of a family, but the disease appears only in the males; the Jews in certain districts of Germany present many examples. There is a remarkable family near Elkton, Md.

Dr. Saveny replied that there were no evidences of hemophilia in the family. The mother was pallid, had red hair, but did not lose much blood in labor.

Dr. Horace Williams had seen a case of obstinate and prolonged hemorrhage after the extraction of a tooth; it was finally stopped by fitting a cork into the alveolar cavity. An infant, aged nine days, was attacked with purpuric spots over the body and bleeding at the naval. To the latter were applied, successively, styptic colloid, tannin, Monsel's solution, Monsel's salt, in powder, and finally, transverse pins and figure-of-eight ligatures; but the bleeding reappeared as soon as the latter came away, and the child finally died from loss of blood.

Dr. R. A. Cleeman had under his care a young man who had previously suffered from profuse hemorrhage for two days, consequent on the extraction of a tooth; the hemorrhage was finally stopped by Dr. Hartshorne, who plugged the cavity with a styptic. Dr. H. advised the young man never again to run the risk of a hemorrhage of any kind, as it would probably prove fatal. Recently he had been suffering severely from a toothache which nothing but extraction could relieve. Dr. Cleeman put him on gallic acid internally, and tannic acid locally, for two weeks before the extraction, which was accomplished without any unusual loss of blood.

In a case of nasal hemorrhage, the anterior and posterior nares were plugged, but then ecchymoses appeared around the eyes, and the plugs were removed; transfusion of a few ounces of blood was employed, and the hemorrhage ceased and did not return; the patient died three months later, of phthisis.

Dr. E. L. Duer considered gallic acid a very valuable remedy for hemorrhage. He would like particularly to bring before the Society the old but neglected remedy, erigeron, or fleabane; the tincture and the volatile oil are very efficient, when used internally, to stop hemorrhage. The oil may be given in doses of ten drops every ten minutes until the bleeding is checked, after which it may be continued at longer intervals until the tendency has passed away.

Dr. Githens had been using oil of erigeron for a number of years, with remarkable success, as an internal hæmostatic. It was far more reliable than any other with which he was acquainted.

Imperforate Rectum.

Dr. Githens had performed an autopsy this afternoon upon a baby, aged twelve days, that had died from occlusion of the bowel. The

anus was perfect, but as no meconium was passed an examination of the rectum was made; the latter was found to be a cul-de-sac about one and a half inches in depth, as a tumid swelling could be felt above; a nick was made at the upper extremity of this cul-de-sac, and gas and meconium escaped; two days later it was found necessary to enlarge this opening, but at no time did any solid fecal matter pass nor did the color of the milk appear in the fæces. Death occurred from collapse, from escape of the contents of the bowel into the peritoneal cavity. At the autopsy the rupture could not be found; the transverse colon was filled with well digested milk, the upper part of the descending colon doubled sharply on itself and was bound down tightly to the posterior wall of the abdomen, there being no meso-colon on the left side; the lumen of the colon at this point was also obstructed by an exaggerated valvula conniventes (?) which formed a septum reaching half across the colon, and had prevented the passage of the solid portions of the fæces below that point; the rectum was distended with some liquid, dark, fecal matter.

A very remarkable circumstance in connection with this case is the fact that a former child of the same parents died at the end of the third day, there having been no discharge from the bowels; and the mother's aunt on her mother's side, had lost five children out of seven from the same cause; one of the five had been operated upon, but the condition returned after the lapse of six months.

Report of Microscopical Examination of Specimens presented at the last Meeting by Dr. Wm. Parish; by Dr. H. Beates.—The specimen removed from the cervix uteri of case No. 2, is carcinoma, of the encephaloid type. The small tumors taken from the uterine cavity of case No. 1, for the relief of continued hemorrhage, prove, on section, to be hyperplastic glandular utriculares, mucous membrane and parenchyma. The intimate relationship of the uterine mucous membrane with the muscular structure is clearly shown, and the features of clinical interest in this instance well demonstrated. The mucous follicles or glands located on the free border in considerable number, indicate that the growths originate from the fundus. The follicles are the seat of active epithelial proliferation and papillomatous degeneration, which latter process, it may be remarked, is *not* characterized by the regular relationship of cells to vessels, seen in typical or benign papilloma, but by large multinucleated, irregularly-shaped cells, arranged in groups, without any apparent regularity or system. This condition is strongly suggestive of carcinoma. The lesó-fibres are found to be infiltrated, in many places, by proliferated epithelium cells, showing that the morbid process involves the parenchyma.

—To promote the cause of temperance in Germany an attempt is to be made to establish coffee-taverns for the poorer classes, similar to those opened in this country. A society has been formed with this object, and a meeting to carry it out has been held, at Frankfort on-the-Main.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Clinical Observations on Albuminuria, Based upon a Study of sixty-two Cases in Private Practice.

BY ARTHUR V. MEIGS, M.D.,

Physician to the Pennsylvania Hospital.

(Read October 4, 1882.)

During the last eight or nine years it has been my habit to keep a record of the examinations of urine I have made. That record now contains notes of between sixteen and seventeen hundred examinations, and a study of it recalls to my mind, with more or less distinctness, the histories of sixty-two persons suffering with albuminuria.*

In a number of instances I have been able to follow cases for a series of years; from this circumstance in particular, the number of years the patients were under observation, I have been enabled to satisfy myself of some clinical facts, particularly in reference to the diagnosis and prognosis in this complaint, which I hope may be worthy of your attention.

That which has most impressed me is the impossibility of making a prognosis, with any degree of exactitude, in most cases of Bright's disease. Of course, in the plainer ones, the decision is easy; if asked an opinion in a case with a large, or even moderate amount of albumen in the urine, with increasing heart failure, and evident decline of strength and vitality, with headaches and the peculiar white complexion of the disease, it is easy to prophecy that such a person will not live long, and the prophecy, nine times in ten, comes true; if called, however, to decide questions of the future for a young man of thirty-two or three, previously well, but for some weeks complaining of headaches, malaise, and boils, and then examination of the urine shows a slight amount of albumen, granular and hyaline casts, and abundance of rather small oxalates, the question of the future is not so easily decided. I have seen such cases go on pretty well for a few months, then suddenly have convulsions, and die in a few days. Again, persons presenting identical symptoms, after being sick a few weeks or months, entirely recover. To my mind it is impossible, in the present state of our knowledge, to anticipate the future, and the patient should always have the benefit of the doubt, and be shown the brighter rather than the darker side of the picture.

I know of three persons in whose urine I found albumen and tube-casts, accompanied with all the other signs of Bright's disease, more than eight years ago, who are yet alive. One is a lawyer in easy circumstances, who was taken sick in January, 1874, when he was fifty-six years of age, with what appeared to be a bad cold, but he had extreme dyspnœa and excessive restlessness and nervousness, although he is usually very self-composed. The dyspnœa seemed greater than could be accounted for by the extent of disease of the lungs, which amounted

* Many of these cases occurred in the practice of my father, Dr. J. Forsyth Meigs, but a large majority of them I saw from time to time myself.

only to a moderate bronchitis; the urine being examined, it was found to contain a trace of albumen, some blood, and tube-casts. It should be said that this man had suffered in previous years with attacks of gravel, when he would pass blood and small calculi. Nearly four years afterwards there was still a trace of albumen in the urine, and granular casts, showing that the condition was by no means merely temporary. Ever since he is liable to severe colds, and always suffers more than common with oppression, although it usually takes the form of a common coryza. He is now sixty-four years old, and an unusually young-looking, active man of his years.

In contrast with this case, a woman of about sixty was seized in the night, having gone to bed apparently in her usual health, with an attack of oppression, and what her physician called congestion of the lungs, so violent that it was thought she would die at once; she, however, rallied by morning. An examination of the urine, made a few days afterwards, revealed the presence of a slight trace of albumen and casts. Four months afterwards there was still a trace of albumen in the urine, and granular and fatty casts, although she was up and about as usual, being merely very weak, having no apparently urgent renal symptoms. At a later examination the trace of albumen was still found, but no casts. About seven months from the first discovery of the disease she had another violent attack of oppression, and died in a few hours. Now what are the points to distinguish these two cases? One died after a few months' illness, and the other, having had apparently the same complaint and almost identical symptoms, is, after eight years and a half, still alive, and apparently, unusually well for his time of life.

In December, 1874, a lawyer in full practice, then about fifty four years of age, was taken with an attack of acute catarrhal pneumonia, and was also found to have albumen and tube-casts in the urine. He was sick all that winter and the following spring, the urine constantly containing albumen and granular and hyaline casts. The albumen and casts were found in the urine during 1875 and 1876, and part of 1877. On May 2d, 1877, about two and a half years from the onset of the disease, there was at last no albumen found, and the microscope revealed nothing abnormal. Since that time, although the urine was examined in 1878, 1880, 1881 and 1882, there has never been found either albumen or tube casts, and the patient. now a man sixty-five years of age, enjoys very good health, having had no return of the disease in more than five years.

The third case is a woman, whose father, brother, and two sisters have died of the same disease. She has had a trace of albumen and hyaline and granular casts in her urine since March, 1874, when she was about thirty-one years of age. I have records of this condition in 1874, 1876, 1879, 1880, 1881, and 1882. In February last she caught cold, and seemed for some time on the verge of a severe renal attack, having coryza, so that her nose was almost entirely stopped, and there were bronchial râles heard in the chest, but an amount of dyspnœa, seemingly out of all proportion to the extent of the disease, that could be detected by physical exploration; the albumen in the urine also increased very much in quantity. In some weeks, however, she recovered, and this summer seems in her usual health.

The father of this patient had a severe attack of hepatic colic, and passed several gall-stones, in 1877, but afterwards he continued in pretty fair health for some time. On May 9th, 1879, a trace of albumen was found in the urine; this continued to be present at succeeding examinations, but no tube-casts were found at this time or afterwards, although they were carefully sought for, and about December, 1880, eighteen months from the original discovery of his disease, he succumbed to an attack of uræmic convulsions, being seventy years of age. A son and two daughters of this man died of the same disease some years before. The son, after having had dropsy, lived for several years in tolerable comfort, until a severe cold proved fatal. With the history of this son and one of the daughters I am not familiar, but the third one I saw, and she died in convulsions. The condition of this person before her final illness, which lasted only a few days, was in no way different from that of her sister, who is still living, and has had the disease for nearly nine years, and the attack which the surviving one had last March was exactly like those of which I have frequently seen other people die.

I maintain, therefore, that with our present knowledge it is impossible, in doubtful cases, to prognosticate what the result will be, and that for the patient and his family, as well as for the credit of our profession, we should be very guarded in our prognosis. The presence of albumen and tube-casts in the urine, even when found for so long a time as two years continually, is not, as shown by one of the histories I have detailed, a reason why we should necessarily give a fatal prognosis, and this is particularly the case when the patient is a person past middle life. In the face of such authorities as Beale and Grainger Stewart, many practitioners think the microscopists can better judge (by examining the urine) of the stage and form of Bright's disease they have to deal with than they themselves can. Grainger Stewart is emphatic upon the subject. On page 271 of the American edition of his work on "Bright's Disease," he says: "Some authors attach great importance to the tube-casts. They are of undoubted value in establishing the existence of Bright's disease, considered generically, but they afford comparatively little assistance in the differential diagnosis of the different forms. Any form of tube-cast may occur in any form of the disease, and at almost any stage. Indeed, all the leading varieties may occur simultaneously in one case." Beale says (Kidney Diseases, Urinary Deposits and Calculous Disorders), "Dr. Basham thinks he can judge of the stage of Bright's disease by the character of the urinary sediment. I wish I could agree with him in this conclusion. The more carefully the matter is investigated the more convinced am I that it is unsafe in many cases to attempt to draw inferences as to the stage of the disease from the character of the urinary sediment only. Nothing but a careful

consideration of every point connected with the case will enable us to arrive at a general conclusion concerning the state of the disease. . . . Dr. Basham says: 'The most untractable and hopeless form of *morbus Brightii* is that represented by the presence of the fatty or oily cast.' This statement requires some qualification, for although it is quite true that some of these cases are terribly and rapidly fatal, it must be admitted that some live for twenty years or more, and die at last of other disorders." With regard to the presence of oily casts in the urine, and it is upon their discovery that microscopists found their gravest prognosis, Dr. George Johnson says (Lectures on Bright's Disease, New York, 1874), "The appearance of oily casts and cells excites less alarm now than it formerly did. It indicates that in certain parts of the kidney the secreting cells and inflammatory exudations are undergoing fatty transformation; but I have seen many cases of complete recovery after oily casts and cells in great numbers had appeared in the urine continuously for many weeks."

A very common symptom of renal disease, and one upon which there is not much stress laid in the majority of books upon the subject, is dyspnœa. Whenever a patient is found suffering with dyspnœa, and particularly if there is great nervousness, and loss of self-control, and anxiety, with no other fully sufficient cause for its existence, suspicion of renal disease should be aroused, and the urine examined, even if there are no other symptoms whatever pointing toward a lesion of the kidney. These attacks of dyspnœa frequently come on with great suddenness in persons who have not considered themselves sick, and such attacks are often quite rapidly fatal. This condition has been described as renal asthma, but I believe it much more common than is usually supposed. Another symptom of Bright's disease, which I have frequently noticed, and have never heard described, is coryza, of such a character that it gives rise to very much greater distress than any ordinary cold in the head; with this there is not much discharge from the nose, but the patient complains that he can get little or no air, except through the mouth, this being accompanied with excessive oppression, much more than the condition would seem to warrant. This symptom was first called to my attention by my father, Dr. J. Forsyth Meigs, in a case we saw together about nine years ago.

The suddenness of the onset, or perhaps it would be more correct to say, of the discovery of the existence of this disease, is often very great. In one instance, I knew of a young man, previously supposed healthy, seized with a convulsion while sitting at the supper table, after he had finished his day's labor as a wagon driver; this was followed by others, and the case ended fatally in a few days. In a second case, I was called upon by a young woman to explain a swelling of the vulva, with which she was suffering; examination of the urine revealed the existence of a large amount of albumen; this continued for some time, but after prolonged use of iron, her condition improved, and she had apparently fair health, until about two years later she became pregnant, and died within a few days after the birth of her child. In a third case, a man fifty-four years of age was seized in the night with epistaxis, a thing he had not had since he was a boy; examination of the urine revealed the cause, and about six weeks later he was found one morning, insensible, in the bath tub; examination showed that he had right hemiplegia, and he died in three days; a vessel in the brain had ruptured, presumably from the same degeneration which six weeks earlier had caused the nose to bleed. On the other hand, the insidious nature of this disease and of its onset is a matter of such common report, that I will not weary you with any cases illustrative of this fact.

The existence of oxaluria, or of uric acid lithiasis, is a prolific source of mischief to the kidney. The deposit of oxalates, or uric acid in the kidney, and its passage outward, occurs most frequently in persons who are large eaters, living an inert life, and taking but little exercise. Such people are common among the rich in large cities, and I have seldom failed to find tube-casts in the urine of any one who passed gravel for any length of time, whether oxalates or uric acid, even if the calculi were microscopic in size, and this commonly before any albumen was to be found. Later, if there is any considerable amount of gravel passed, albumen and blood will be found in the urine. If the attacks of gravel occur often, they are apt, at last, to be followed by Bright's disease, directly caused, probably, by the mechanical irritation of the lining membrane of the tubules of the kidney, by the sharp edges of the minute calculi passing through them.

It cannot be proven by statistics, and yet I think there is strong ground for believing, that the proportion of deaths caused by affections of the kidney is greatly on the increase. The tendency of modern life seems to be such that a larger number of deaths are caused by degenerative processes, and less by acute disorders. In former times, children were less delicately reared, and a larger proportion of the frailer ones, probably, died from exposure and want of care; now, beginning at childhood, and continuing up to old age, we are much more careful to avoid exposure, and are more self-indulgent, at least, as far as our bodies are concerned. Who, in modern times, except the professional athletes, would undertake the physical labors of the Emperor Charles V, of Germany, of whom Motley says, that he was able to tell, at a time when all journeys were made on horseback, or by boat, "of his nine expeditions into Germany, six to Spain, seven to Italy, four to France, ten to the Netherlands, two to England, as many to Africa, and of his eleven voyages by sea!" Now-a-days, the majority of city men are in their places of business all day, and take but little exercise, eating as much and as rich food as in former times, and drinking not a little withal. The natural and necessary consequence follows, that after years of this kind of life, the excretory organs degenerate; first the kidney, which is the common sewer of the body, and, like the heart, has to do continual work, from the hour of birth until the hour of death. It is a common thing, in modern life, to see a man naturally robust and gifted with a large appetite, become more inert

as years go by, when he will gradually give up his active exercise, until finally he takes none; still the eating and drinking go on, and he becomes fat and sluggish; finally he loses health, and then examination shows that degeneration is beginning in the kidney. I could instance several cases of the kind, but my space will not allow me.

The drift of my paper has been to try to establish that we should, in all ordinary cases of albuminuria, be very guarded in our prognosis, except when it is self-evident that the case must be rapidly fatal. I have now under observation, fifteen persons, seventeen, if I count two who have albuminuria alternating, or parallel with, diabetes mellitus, who have been suffering with this complaint for a greater or less length of time. With three of them the disease began nearly nine years ago, and they either have it now, or have entirely recovered from it, after more than two years' continual duration; yet in regard to no one of them do I feel able, even in my own mind to guess, much less to formulate an opinion, as to how much longer they may live. There are absolutely no data, if such cases are considered in the light of the experience of the sixty-two I shall mention, upon which to found a positive prognosis.

Another observation I have made, is in regard to the death of very old people. We are all agreed, I presume, that when a very old person dies, and we report the death as one of old age, it is because we are unable to put the finger upon the exact part of the old and worn-out machinery that at last refuses to work, and thereby causes all the rest of the mechanism to stop. This direct cause, if sought for, will frequently be found in the kidney. To examine the urine is not always a thing that strikes us, particularly when absolutely no symptoms appear to point toward kidney disease. I have seen a number of instances in which old people seemed to be fading out, as they often do, yet have felt entirely unable to explain to myself any direct cause for the failure, until the urine was examined, when there was found albumen, with granular and hyaline casts, and sometimes a few blood corpuscles. A careful inquiry would perhaps reveal the fact that the amount of urine passed was very small; all this without any other symptom to point toward kidney disease; at the same time, the failure of the patient being very gentle and gradual: or else, as not unfrequently has happened, senile delirium existed, either violent or mild in type, followed at last by death.

In the whole sixty-two cases which I will now summarize collectively, there have occurred twenty-six deaths, thirty-four are, to my knowledge, still living, some in better and some in worse health, and of two I have lost sight.

Five were cases of ordinary acute desquamative nephritis, with the occurrence of one death and four recoveries. In one instance, a child, there were two attacks, two years apart, the first being unaccounted for, the second following scarlet fever; the second case occurred after scarlet fever; the third after diphtheria; the fourth was in a young man, apparently healthy previously, and now in good health; his attack only lasted a short time; the fifth and fatal case was in a boy of about fifteen years of age, and came on while he was at boarding school, the onset being insidious, and the disease progressing from bad to worse until death occurred.

Four cases seemed to be caused by the passing of gravel, principally oxalates. These people are still all living, although they have had albumen and casts present in the urine, on and off, for varying lengths of time; two of them for six years past, one for seven years, and the fourth has had two attacks of nephritic colic, about a year apart; on each occasion, albumen and granular casts, uric acid and blood corpuscles were found in the urine.

Twenty-two cases I class as of ordinary Bright's disease, there being probably contracted kidney in the majority of instances, and of them, fourteen are dead. I made no post-mortem examination in any one of these cases. In most of these cases (seventeen of them) the onset was insidious, there being no illness to mark the beginning of the disease; in one, the patient was seized with a convulsion at the supper table, having been supposed previously to be in good health; in a second, there was a violent attack of congestion of the lungs, with terrible dyspnœa during the night, the patient, a woman, having gone to bed thinking herself in good health; in a third there was dyspnœa and congestion of the lungs occurring suddenly; in a fourth the condition of the kidneys was discovered concurrently with an attack of catarrhal pneumonia; a fifth was a man who had had attacks of nephritic colic. He had a violent attack of congestion of the lungs, with bronchitis and dyspnœa, and was found to have albumen and casts in the urine, which condition continued, on and off, for four years; he is now in apparently good health, although the first attack was nearly nine years ago. Of these twenty-two cases, two were in one family, one soon dying, and of the other I have lost sight; two in another family, one dying and the other, I think, being still alive, although the disease was discovered three years ago; five cases occurred in another family, the father, son, and three daughters. The father and mother of this family had ten living children, five reaching adult life, one died of consumption, and the other three, and the father, of Bright's disease, the surviving daughter has had the disease for nearly nine years. In another family there were three cases, all women; one died, having had uræmic convulsions, and the other two still live, both having had the disease for about three years. A brother has now cancer of the rectum. The mother is still alive, and although seventy-four, enjoys good health. The father died at quite an advanced age, but I do not know of what disease.

The next twenty-two cases I must classify as unaccountable; eighteen of them occurred in persons over sixty years of age, and the other four were well on in life; one was over ninety, three over eighty, and two over seventy years of age. Of these people only five are dead, and of the five fatal cases, one was the man over ninety, two were over eighty, a fourth was seventy-seven, and the fifth sixty-seven.

The next four cases were of people advanced in life, and they died of general break-down, having in three instances concurrent disease of the heart and kidneys, with implication of the lungs, and the fourth had renal and brain disease.

In two instances there has been albuminuria with diabetes mellitus; in one, sugar was discovered in the urine six, and in the other four years ago. Since then there has been sometimes sugar, and at others albumen, at times both at once, in the urine of these two women. In neither instance have tube-casts ever been found. I mention these two cases in a paper on albuminuria, because both have frequently had albumen in the urine, and I confess myself unable to explain the phenomenon, the quite frequent presence of albumen in the urine, without tube-casts, or any other sign of renal disease; and yet I can hardly believe the albumen to be merely due to cystitis, for if that were so, it should be constantly present.

In one instance, I have followed for four years the history of a man who drinks to excess. At the beginning of, and for a time before, his attacks of delirium tremens, while he is consuming alcohol freely, he often has bloody urine, which will contain tube-casts of all the varieties at different times, fatty, hyaline, and granular. When he ceases his consumption of alcohol, as he has quite frequently done for two or three months at a time, the urine becomes normal, as far as chemical tests and microscopic examinations will reveal its condition. In the light of this case, how can we believe that the abuse of alcohol does not produce renal degenerations? Is not this man sure to die of Bright's disease, if he continues his indulgence in alcohol?

Another case was a man over fifty years of age, who was seized with rheumatism; he progressed badly, and was much more sick than the amount of rheumatism would seem to warrant, and at last, after about three weeks, died, having obstruction of the bowel and inflammation of the kidneys, as shown by the presence of albumen and tube-casts in the urine; also hydrothorax, and extreme stupor, which seemed uræmic. This man had had an attack of influenza about three or four weeks previous to his fatal illness. Can there be any connection between the severe influenza and the rheumatism, and renal inflammation and obstruction of the bowel, of which this patient died?

The last case I will mention was a boy, who died very suddenly, of congestion of the lungs, probably the first stage of pneumonia. A trace of albumen and granular casts were found in his urine, which was obtained a short time before death. This boy was about sixteen years of age, and did not seem much sick on the afternoon of one day, being up and dressed, the next morning dying, in a state of maniacal delirium, with his lungs extremely congested. There was, unfortunately, no post-mortem examination made. This case would seem one in which the pulmonary affection was primary, and yet it might be that he had a latent contracting kidney.

There has been much said of later years about kidney disease without the presence of tube-casts in the urine, and of the presence of casts without albumen. I may say that I have frequently found tube-casts in the urine when the most careful chemical examination failed to detect any albumen, and *vice versa*, have failed to find any casts at all, when the event proved the existence of renal disease.

The subject of treatment I have not even mentioned in my paper, although much might be said about it, because I have already trespassed too long upon your time.

In conclusion, I will briefly recapitulate the points which it has been my endeavor in this paper to prove.

First, that in no ordinary, uncomplicated case of Bright's disease, should a prognosis of speedy death, or even of incurable disease, be given, for I have related cases in which the disease was chronic, lasting more than two years, and which ended in complete recovery, and others in which the person affected has lived nearly nine years.

Second, that dyspnœa, usually taking the form of renal asthma, is much more common than is usually supposed, and when properly appreciated is a valuable diagnostic sign of the disease; also that severe coryza is a complication or accompaniment, and has a diagnostic value.

Third, that Bright's disease, as a cause of death, is on the increase.

Fourth, that it is a very common cause of the deaths of old people, probably being the direct cause in many deaths reported as of old age.

Fifth, that the passage of gravel, even when microscopic in size, but particularly if large enough to cause nephritic colic, is a prolific cause of the disease.

Sixth, that the occurrence of tube-casts in the urine without, or in advance of, the presence of albumen, is very common, and *vice versâ*, persons may die of Bright's disease, and the most careful examination fail to show any tube-casts, although there may be albumen constantly present in the urine.

Seventh, that the abuse of alcohol is certainly a cause of kidney disease, as proved by the case I have related, in which it has, again and again, caused hemorrhage from the kidney, with the temporary presence of albumen and tube-casts in the urine, disappearing again with the cessation of its consumption.

Pyrogallic Acid in Treatment of Venereal Ulcers.

Pyrogallic acid, recently introduced by Dr. Jarisch, of Vienna, has been used with success in the treatment of venereal ulcers, by M. Vidal, at the St. Louis Hospital, and M. Terillon, at Lourcine. The following unguent is employed at Lourcine:—

℞. Acid pyrogallic, ʒ x
Amyli, ʒ x
Vaseline, ʒ iv. M.

This unguent should be fresh and well guarded in a glass-stoppered bottle.

As fatty dressings to venereal ulcers are often inconvenient, M. Terillon recommends the following composition:—

℞. Acid pyrogallic, ℈ j
Amyli, ʒ j. M.

This may be directly applied to the ulcers.

These applications, made daily, notably abridge the duration of treatment.

Periscope.

Nephrotomy and Nephrectomy for Pyelitis.

In the *Lancet*, Dr. George Elder records a case of scrofulous pyelitis occurring in a woman aged 36. Physical examination of lungs gave evidence of tuberculous disease. She first experienced severe pains down the left side and leg; painful micturition of turbid and scanty urine; no hæmaturia; to these were added, rigors, fevers, night sweats, occasional sickness, anorexia, progressive emaciation and loss of strength. The urine was strongly ammoniacal, muco-purulent, and containing triple phosphates in abundance. She did not pass more than sixteen ounces in twenty-four hours. She had a large, fluctuating, abdominal tumor, which was examined, under ether. Dullness extended from the anterior superior iliac spine up to and continuous with the cardiac area, and in a transverse direction from an inch to the left of the umbilicus round to the spinal column. The impression was given that the kidney was converted into one large abscess. Nephrotomy was performed by the usual lumbar incision, and a large quantity of curdy pus escaped. The kidney had been converted into two sacs. The shock was slight, and for a few days the urine was freer from pus than formerly; the wound discharged freely.

"An attack of septic pleuro-pneumonia of the right base, which all but ended the record of the case, coupled with the want of benefit following the nephrotomy, strengthened my resolve to extirpate the kidney as soon as the patient's condition warranted it. This I did, on June 20th, by enlarging the former incision and supplementing it by a crucial. There was very great difficulty in enucleating the kidney from its capsule, mostly experienced at the point of insertion of the vessels. The friability of its structure also contributed to this, and at the same time gave rise to copious bleeding, which pressure by means of sponges checked. I tied the blood vessels and ureter *en masse*, with strong carbolized Chinese silk, and then cut away the kidney. Under the strain of the ligature, the friable tissue of which the pedicle was composed gave way, and for a time the hemorrhage was appalling. A second and then a third were applied higher up, with the effect of stopping all bleeding, except from a few small arteries, which were separately ligated. A few loosely applied metallic sutures, simply used to approximate the edges of the wound, after it had been washed out with carbolized water and tamponed, finished a very tedious operation. Through failure of the spray producer it was not done antiseptically.

"The shock after the operation was extreme, so much so that for several hours it was doubtful whether the patient would rally. Frequently repeated rectal injections of pancreatized beef tea and brandy stood her in good stead. For the first forty-eight hours the scantiness of the renal secretion assisted in making the outlook more gloomy, but at the end of this time the quantity became natural in amount. After the operation its quality became normal, and has remained so ever since. With the above exceptions the patient made an uninterruptedly good recovery, and when she was discharged from hospital, on account of the annual cleaning, she had got quite plump, and there remained of the wound only a small sore.

"*Remarks.*—This was a very unpromising case upon which to perform such a grave operation, not only on account of the prostration induced by the condition for which relief was sought, but also because of the state of the chest and the drinking habits of the patient. I regret that the major operation was not at first performed, as by it time would have been saved and the inter-current attack of pleuro-pneumonia averted. The variations in temperature before alluded to ceased with the nephrectomy, as also the hemi-hyperidrosis, and before her discharge there was an improvement in the chest symptoms."

Fracture of Skull in an Infant—Death.

In the *Medical Times and Gazette*, Mr. Godlee reports the case of a child aged one year and seven months, who fell a distance of only two feet, striking the side of his face. He was stunned at first, but soon came round, and cried for about five minutes, after which he became drowsy; he retched several times, but was not actually sick. Some blood was flowing from left ear, which in a few minutes gave place to a watery fluid. On admission to hospital he was pale and drowsy; some tenderness behind left ear, pupils equal and reacted to light, no nervous symptoms of any kind. On the sixth day general convulsive movements of the limbs and face set in; in the afternoon the temperature ran up to 105°, and at 6 P.M. the child died.

At the *autopsy* an extensive fracture of the skull was found, beginning about the middle of the left parietal bone, in a bifid extremity, and extending downward to the back of the meatus externus; after passing a little forward, so as to reach the roof of the meatus, and separating the tip of the auditory process, it passed along the meatus, rupturing the upper and back part of the membrana; it then again bifurcated, the posterior part passing through the internal auditory meatus to the jugular foramen, the anterior extremity towards but not quite reaching, the foramen ovale. There was a considerable amount of pus in the cavity of the arachnoid, principally on the left side and at the base of the brain, but not extending to the upper parts of the hemispheres. Beneath the arachnoid, however, there was a copious effusion of puriform lymph, most abundant about the base of the brain, but extending in less amount to the sides and front of the hemispheres, and reaching to a smaller extent as far as the vertex. It extended along the medulla, and for two inches along the spinal cord; it also followed the velum interpositum into the third ventricle; but the

lateral ventricles did not contain an excess of fluid, and their contents were not abnormal. The vessels of the base were searched, both with the naked eye and the microscope, for tubercle, but no sign of it was found. The other organs, with the exception of the lungs, which were congested, showed no signs of deviation from health.

Remarks.—It is to be noted, in the first place, that severe fractures of the skull in children of this age are by no means common, their soft, elastic bones being indisposed to fissure in the same way as those of an adult. In the second place, it is remarkable that such an extensive fracture should result from so trivial an injury. The question of the possibility of a fall of two feet producing such a result as was found, suggested itself as one that might, under certain circumstances, have had a very interesting medico-legal bearing. But the most important lesson to be learned from this and similar cases is, that if a fracture of the skull ruptures the membrana tympani, and also passes across the internal auditory meatus, it constitutes not only a compound fracture of the skull, but a compound fracture of the skull communicating directly with the cavity of the arachnoid. No condition can be possibly conceived more favorable for originating a septic meningitis. It is surely wise to treat such a fracture on antiseptic principles, namely, to clear away all wax and discharge from the ear, and then to inject the meatus constantly with some one-to-twenty carbolic acid lotion, and to apply either a gauze or iodoform dressing, changing it when it becomes soaked. I can testify to the safety with which this may be done, and to the efficiency of the proceeding if it be done early, and not, as in this case, when the mischief has already occurred. It may be objected that even if the meatus externus be purified, the fracture still communicates with the external air through the Eustachian tube. This must be granted, but there is no more reason to suppose that organisms exist in the tympanum, than that they are to be found in the bladder, which we know is, under ordinary circumstances, not the case; the healthy mucous surface of the Eustachian tube, like that of the bladder, no doubt preventing the spread of these low forms of life along their surfaces. The blood which flows from the nose and mouth in many of these cases no doubt passes along the Eustachian tube, and if this takes place to any great extent it is perhaps likely that the fracture would be contaminated through this source; but, seeing how seldom prolonged bleeding takes place from these cavities, I would strongly urge that the line of treatment mentioned should always be adopted.

Operations for the Cure of Hernia.

In the course of a long article on this subject, in the *Annals of Anatomy and Surgery*, Dr. William Dunnet Spanton, of England, says:—

As a single matter of observation, and, in spite of the positive statements to be found in most writers to the contrary, it would appear that an infinitesimal proportion of cures are effected by the use of trusses. In the London Truss Society, out of a total of 96,886 cases of reducible hernia, only 4387, or 4.53 per cent., are said to have been cured in this way. A truss can only act by direct pressure on the part to which it is applied. But to close a hernial opening we need something more than this. As I have said, the moment the pressure is taken off the rupture descends afresh, and this must necessarily be so as long as the canal remains patent. If, therefore, it be possible to combine the filling up the canal itself with organized tissue at the same time that the tendinous boundaries are firmly approximated, we shall in this manner secure a much firmer support than in any other way.

The more recent procedures, having this object in view, consist of a variety of modes of ligature on the one hand, and my operation with the screw (or strephotome), on the other.

With regard to my own operation, I have now a record of over sixty cases, all of whom have recovered. The patients varied in age from five months to thirty-four years, and the herniæ differed in size, from small, tense ones to enormous, lax ones. All were of the inguinal kind, some oblique others direct, and a considerable proportion were congenital. An incision is made, large enough to admit the forefinger through the skin of the scrotum at the fundus of the hernial sac, an inch and a half or two inches below the pubic spine. The sac, with the fascial tissue covering it, is then separated from the skin, by passing the knife or the handle freely around the internal surface of the wound, until a sufficient extent has been separated to permit the finger easily to invaginate the sac into the hernial canal, which is readily accomplished by pushing the sac, with the left forefinger, up to the internal ring.

After carefully examining the condition of the parts within reach of his finger, especially with regard to the position of the blood vessels and the boundaries of the aperture, the operator retains his forefinger in the inguinal canal, thereby protecting the spermatic cord, which lies below his finger, and at the same time closing the internal ring so as to prevent any protrusion of the bowel. Sometimes, with a very patent ring, it is necessary for an assistant to place his finger externally on the groin to make perfectly sure of this, especially if there is any cough or struggling. It is, however, wiser to wait a few moments, and to let the patient become quiescent before proceeding further. Then, holding the strephotome firmly in the right hand, the surgeon thrusts the point through the skin of the groin at that part of the surface which corresponds to the outer pillar of the internal ring, which is also pierced by the point, which now comes in contact with the left forefinger. Having given the screw a turn, the point is made to pierce the invaginated sac, and pushed on through the internal pillar (conjointed tendon) as high up as can be safely reached, the left forefinger carefully guarding the

point of the instrument throughout. Another turn is now made, causing the screw to pass through the invaginated tissues and across the pillars of the external ring as many times as the length of the canal and the nature of the case will permit. The left finger is gradually withdrawn as the point passes downward and outward through the opening in the scrotum, the spermatic cord lying behind, and slightly compressed by the gradual tightening of the hernial canal. The point of the screw is then protected by a small india-rubber ball, and the handle lies flat on the outer surface of the abdomen. The scrotal wound is closed by a single wire or hair suture. In from seven to ten days the screw can be removed, and a compress used to keep the parts in position.

Digestion of Meat.

The *Lancet* says:—

It is well known that the digestion of different kinds of meat is the more easily effected the longer the time that transpires after the death of the animal. The explanation given is, that by keeping, the muscular fibres become gradually dissociated; they soften, become less compact, and consequently are more soluble in the gastric juice. According to physiologists, however, it is not considered advisable to wait until decomposition sets in, because, in addition to its losing a great part of its nutritive qualities, the meat becomes so nauseous that no amount of cooking, or the addition of condiments, will much improve it. MM. Pasteur and Lemaire, in an interesting paper lately submitted by them to the Academy of Sciences, stated that meat too far advanced, or what is termed "faisandée," is most unwholesome, and it is a mistake committed daily by sportsmen to wait until the game gets into this condition, for it is then simply unfit to be eaten. The above-named biologists have shown that tainted meat contains animalcules, which do the work of transformation and destruction; and as it is difficult to ascertain exactly the extent of putrefaction that the meat has undergone, one is liable to consume it just at the moment when it should be rejected. M. Pasteur and other micrographers are of the opinion that these animalcules, of which there are no less than thirty species, are of the same nature as those that are found in living animals suffering from virulent maladies, such as charbon, etc.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Charles N. Hewitt's address, as President of the Minnesota State Medical Society, makes a pamphlet of 24 pp. It is in favor of a fixed standard of preliminary education, and a fair examining board.

——A study of the manner of transmission of syphilis in utero makes a pamphlet of a dozen pages, by Dr. Hugo Engel, of this city. His observations are acute and well worth reading. His favorite treatment is by mercurial inunction.

BOOK NOTICES.

Essentials of Vaccination. By W. A. Hardaway, M.D., etc. Chicago. Jansen. McClurg & Co. 1882. Cloth, 8vo, pp. 146. Price $1.00.

The beneficent discovery of vaccination is daily becoming more and more appreciated, in spite of the opposition to it manifested in certain quarters. The volume before us adds to the conclusiveness of the testimony as to its valuable prophylactic powers. Much of the author's space is taken up with the production and use of bovine virus, and on this account his essay will have especial value. In spite of all that has been written and spoken on the methods of propagating and employing this form of virus, an astonishing amount of ignorance about it prevails, and for that reason we hope Dr. Hardaway's book will be generally read. We have noted only one point where he seems to be at fault himself as to how vaccine matter should be used. That is (p. 110) where he says "the habit of using one quill for two persons is filthy and dangerous." It is singular that he did not appreciate that when one quill is used for two persons it is first *split in two* and each half used separately.

Rheumatism, Gout, and Some Allied Disorders. By Morris Longstreth, M.D. New York. William Wood & Co. (Wood's Library of Standard Medical Authors.)

Dr. Longstreth treats of the forms of rheumatism, its causes, pathology and ordinary course, its individual symptoms and peculiarities, complications, morbid anatomy, prognosis and treatment. The last three of the nineteen chapters of the work respectively, are on chronic articular rheumatism, gonorrheal rheumatism and gout. The author's opinions are carefully weighed, and his language even too cautiously non-committal in various passages. He writes from judicious observation, and his work merits careful reading.

The Diseases of Women, Their Pathology, Diagnosis and Treatment, including the Diagnosis of Pregnancy. By Graily Hewitt, M D. Fourth American edition. P. Blakiston, Son & Co. Price, paper, $1.50.

The work of Dr. Hewitt has been before the public more than ten years, and has been well received by the profession, both here and in England. The present cheap edition, with the author's latest revision, cannot fail to extend and confirm this popularity. It is neatly printed and contains 132 illustrations.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D.,
JOSEPH F. EDWARDS, M.D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A PHILOSOPHER'S OBSERVATIONS.

As we have had a philosopher, and many think a great philosopher, among us, "takkin notes," this summer, to wit, MR. HERBERT SPENCER, it becomes us to collect with due diligence the pearls of wisdom which he lets drop from his lips.

Several of these have a medical bearing, and to them we give our attention. He made a speech in New York shortly before he sailed, in which he spoke of the characteristics of Americans. Among other things he said:—

"Everywhere I have been struck with the number of faces which told in strong lines of the burdens that had to be borne. I have been struck, too, with the large proportion of gray-haired men, and inquiries have brought out the fact that with you the hair commonly begins to turn some ten years earlier than with us. Moreover, in every circle I have met men who had themselves suffered from nervous collapses due to stress of business, or named friends who had either killed themselves by overwork, or had been permanently incapacitated, or had wasted long periods in endeavors to recover health. I do but echo the opinion of all the observant persons I have spoken to, that immense injury is being done by this high-pressure life—the physique is being undermined."

This was not a passing thought, but Mr. SPENCER went on to elaborate it with his customary fullness of illustration and force of expression.

There is no doubt a certain amount of truth in it. There is a great deal of high pressure in certain centres of American life; there is fast living in every sense in certain strata of society. But are we, as a nation, much given that way?

In spite of all those respected neurologists who have so much to say on this subject, and whose reiterated statements Mr. SPENCER did but echo, we do not believe it.

It is highly characteristic of a New York doctor to be ignorant that any part of the American nation lives outside of New York City; it is a venerable trait of travelers to judge all of a country by the few specimens or classes they see in a few weeks' or months' trip.

If Mr. SPENCER wished to see American life as it is carried on by the great mass of our fifty millions of people, he should have had us pilot him to an interior town of Pennsylvania, or some county seat in Virginia, or to some cross-roads general store in any one of thirty States, and have there passed a few weeks. If he had not found a life as dull, as monotonous, as free from nervous strain and high pressure, as any he had ever seen, then we are out in our reckoning. Yet it is just this life that forty-eight out of our fifty millions lead.

Of course, take the two or three greatest cities of any prosperous nation, and the two or three busiest streets, and the hardest brain-working classes in these cities, and they are under an unhealthy degree of pressure. But how absurd for a man, especially a philosopher, to be led astray by such a narrow and faulty generalization as to suppose what is true of these few is true of the mass! Yet that is just what Mr. SPENCER has done.

As to his supposed facts, that men grow gray sooner in the United States, that they suffer more from nervous collapse, that more kill themselves from overwork, there has never been, and is not now, any evidence that any of these are so. There is plenty of testimony to the opposite

statement, that our people are better fed, better clothed, have healthier lives, bodies as strong, and a surer prospect of a green old age, than the English, German or French in their own homes. Are we asked where is this testimony? We reply, where it has been to the interest of powerful and wealthy corporations to get it accurately, for business purposes, not for the sensation of an after dinner speech. We mean the Life Insurance Companies. Their tables show that the expectation of life is, in this country, on the grand average, rather better than in any of the three countries named, and in special fields very decidedly better.

So much for the value of all this talk about physical deterioration in the United States, and so much for the "broad and deep generalizations" which some philosophers indulge in about a vast nation and its constitution, after they have been dined and wined by a very select circle in one or two of its great cities, and have stayed over night at several of its finest hotels!

THE LATEST ABOUT BACTERIA.

This time it comes from America.

Dr. Formad, of Philadelphia has made some experiments, from which he is led to believe that, contrary to the generally accepted view, bacteria are not the cause *per se* of disease, but are merely the vehicle of contagion, the means by which the poison of certain diseases is carried from one organism to another. He has found the tubercle bacilli of Koch, or, at least, bodies identical with them, in the sputa of non-phthisical patients.

He has taken matter infested with the diphtheritic micrococci (first demonstrated by Professor Wood and himself), and has succeeded in producing the disease in animals, while micrococci from the very same specimen, *after a thorough washing in plain water*, were perfectly harmless.

He believes that bacteria exist in all nature, and that, even when charged with the elements of disease they cannot produce the disease unless they find a resting place in some body that is, on account of some unexplained conditions, a suitable pasture for the growth and development of the particular disease.

This view, which seems to be a very rational one, has two important practical bearings.

In the first place, it teaches us very forcibly the value of water as a disinfectant, and in the second place, it lends much additional force to the idea that infectious diseases are due to chemical influences, which theory, if demonstrated, will do much toward increasing the potency of our therapeutic resources.

If these bacteria carry certain elements that are capable of producing disease, it is not unreasonable to hope that chemistry will step in and tell us the chemical nature of these poisons; from this standpoint it will be but a step to name the chemical that will prove the antidote, and by this process can we arrive at the most rational treatment of infectious diseases. Dr. Formad promises to have more to say on this subject, and we look forward to his researches with interest, for it would seem that he is on the right track.

NUISANCES.

A correspondent writes us, from Ohio, as follows:—

"Please give us your opinion of the following case:—

"A business room in our town is occupied by a clothier; the room (cellar) below is occupied by a lot of *loud* Swiss cheese. The merchant says the odor is exceedingly offensive to him, and complains to the town council, and wants said body to pronounce, not the cheese, but the cheese stored in the room in such close proximity to his place of business, a nuisance, on the ground of the *unhealthfulness* of the odor and the dampness caused by the daily sweating of the cheese.

"Having been appealed to in regard to the above matter, I took the position that the air of the store-room being impregnated with the odor emanating from putrefactive changes brought about in the fats and caseine in the process of thorough ripening the cheese, is not a fit medium for constant consumption by the lungs of the storekeeper. Am I correct?"

Of course he is right. It is a fundamental and incontrovertible principle of sanitary science, that all or any organic decomposition must, and will, produce, as an accompaniment of this change, as a necessary condition of retrograde

metamorphosis, a condition of the atmosphere that is inimical to a perfect state of animal health.

It matters not whether the decaying organic material be a small cube of cheese or an elephant; the difference is only one of degree, and not of kind.

We need not discuss whether these enemies to health that are produced by organic decomposition are bacteria, or gaseous, or what not! For all practical purposes we know enough, and this knowledge tells us, in no doubtful terms, that all organic decompositions will produce poisons to animal life, and that they must all be declared public nuisances.

DIPHTHERIA.

From the Board of Health, we learn that diphtheria has, within the past two months, become quite prevalent in this city.

One of the most terrible of all diseases, it has succeeded so far in eluding the penetrating grasp of science, and we really know no more about it to-day, that is to say, about its causation and prevention, than we did two decades ago.

It was with the greatest pleasure and pride that we published, last spring, the report of Professor Wood and Dr. Formad, detailing their experience with an epidemic of diphtheria at Ludington, Mich.

They concluded that the disease was caused by a specific micrococcus, and the National Board of Health endorsed their conclusions.

But now, this very same Dr. Formad has demolished his own conclusions. Within six short months since his results were published, he has declared them untrue.

Still, this apparent contradiction of facts will, we doubt not, bear good fruit, for, from what we can learn, it seems certain that these bacilli and micrococci (about which we hear so much), have an important bearing on the production of disease, even though they do not produce the disease per se.

In the meantime, until we learn something more about diphtheria, we must carefully *isolate*, *disinfect* and treat to the best of our limited ability.

LOOK OUT FOR SMALLPOX.

The warning comes from the South; smallpox is prevalent in Chattanooga, Tenn.; so also is it, nearer home. A dispatch from Havre-de-Grace, Md., tells us that Harford county is much excited over the prevalence of smallpox, which was introduced into that community last summer by some men coming to work in a canning factory.

You must ever bear in mind that the causative agent of smallpox can be carried great distances and produce the disease. A man may come from a region in which the disease is prevailing, and while perfectly well himself, may carry in his clothing, his beard or his hair the seeds of smallpox, thus constituting a nucleus from which may originate a most devastating epidemic. The following fact must ever be borne in mind: *He who comes at all into contact with strangers is exposed to a greater or lesser degree of danger of infection.* The remedy, or rather the prevention, is to be found in thorough and universal vaccination and re-vaccination.

Notes and Comments.

The Health of Criminal Women.

Dr. E. M. Mosher contributes an interesting article on this subject to the Boston *Medical and Surgical Journal.* His observations cover a period of four years, and were made upon 1704 cases of illness occurring among women committed to the Massachusetts State Reformatory Prison. He divides the women into three classes. Class I. Offences against person and property. Class II. Offences against chastity. Class III. Offences against public order. His conclusions are that

I. Intemperance and unchastity are the two vices which fill our penal institutions with women.

II. The influence of these vices is detrimental to health of body, increasing its susceptibility to disease, and lessening its recuperative power.

III. The diseases which follow as a direct result of these vices are syphilis, alcoholism, dyspepsia, rheumatism and general anæmia.

iv. Morbid conditions of body react upon the moral nature, increasing and perpetuating the tendency to criminality; hence the importance of careful medical supervision as a reformatory measure.

v. More ample provision should be made in all large cities for the isolation and thorough treatment of venereal patients of *both sexes*, either by the addition of special wards to the general hospitals or by the establishment of hospitals for this class.

vi. The women who commit high crimes, that is, larceny, burglary, arson, manslaughter, etc., possess a more sensitive nervous organization than those who commit only offences against chastity and public order.

Diagnosis of Fœtal Monstrosities.

That it would be exceedingly valuable, if the obstetricians were able to recognize before the delivery, if they have to do with an akencephalus, hydroencephalus, or other fœtal monstrosities, is clear. Prof. Calderini (*Ref. Deutsche Mediz. Zeit*, Aug. 10, 1882) has now demonstrated, from theoretical reasons as well—alteration of the pressure and increase of amnion fluid, in consequence of disturbed circulation and different functions of the kidney—as also on three successive cases of his own, that there always exists in cases of fœtal monstrosities hydramnios. This is plausible, and it would be well if further investigations should be made to settle the question, as many a delivery would be made in a different manner, if the obstetrician knew beforehand that he had to deal with a monstrosity.

Subcutaneous Injection of the Salts of Pilocarpin.

The salts used are the nitrate and the chlorhydrate, and the principal physiological effects are; congestion of the skin, principally of the face, exaggeration of the natural secretions, particularly of the salivary and sweat glands; acceleration of the action of the heart; elevation of the temperature at the initial period, which becomes persistent if diaphoresis does not take place later on; there is a more or less marked fall in temperature according to the abundance of transpiration.

Given in ordinary physiological doses, the salts of pilocarpin never induce vomiting or diarrhœa, or the sensation of extreme feebleness often noted after the administration of infusion of Jaborandi. Accidents produced by administration of the salts of pilocarpin at a less dose than one-third of a grain rarely occur, except in patients having some form of cardiac disease.

The injections hardly ever give rise to local accidents; it is well to commence with feeble doses, about $\frac{1}{12}$ of a grain, and gradually increase from that to $\frac{1}{3}$, $\frac{1}{2}$ or even one grain. When the daily dose administered is half a grain or more, it will be well to inject one-half in the morning and the other in the evening. Pilocarpin is employed in therapeutics, where it is thought possible to obtain a very marked curative effect from abundant sudation or from a greatly increased secretion of saliva. Hypodermic injections of pilocarpin have accordingly been principally employed in the treatment of the different forms of dropsy, in pleurisy, bronchitis and pneumonia, and in the treatment of acute articular rheumatism, epilepsy, eclampsia, etc.

Heredity of Sebaceous Cysts.

In the course of a clinical lecture, reported in the *College and Clinical Record*, Prof. S. W. Gross says:—

This man, who has a prominent swelling upon his scalp, tells me that his mother had a similar development. I asked him the question incidentally, because I had in mind the case of a man suffering with mammary cancer, upon whom I operated at this clinic, whose scalp was covered with these excrescences, and his daughter who came with him also had a number of them. Let me say in this connection that many surgeons mention as one of the points of difference between a malignant and a benign growth, that only the former is inherited. They seem to overlook that this also occurs in innocent tumors, even with the simplest of all, the sebaceous cyst.

Removal of Warts.

Dr. Unna, of Hamburg (*Monatschrift Prakt. Dermat.*, 3, '82), had a young girl under his charge, whose dorsal surfaces of both hands were the seat of over a hundred warts, daily more making their appearance. He made on gauze tissue a plaster mass, which contained 10.0 grm. arsenic and 5.0 grm. of mercury. This was kept on during day and night. Two weeks later all warts had disappeared and the healthy skin was seen. The cure here is not established by necrosis and dropping off of the excrescences, but like nature's spontaneous cure, by resorption.

We ourselves used to make cauterization our main treatment for the removal of condylomata.

A year ago, a patient came to us, who, besides suffering from icterus, due to catarrhal inflammation of the bile ducts, was affected with condylomata also. As the latter were very large, preventing the prepuce from being drawn forward, their removal was desirable. They gave rise to an annoying itching and to a fetid odor. Not wishing to operate on them while the patient still had the jaundice, we told him to dust the parts daily with

℞. Hydrarg. muriat. mit., ℥j
Acid. borac. pulver., gr. x. M.
Fiat pulvis.

and were not a little astonished to find three weeks later not a sign of them left. They were all absorbed. Since then we have often had occasion to use this powder, and invariably with the same good success.

Angina Pectoris—Death.

Dr. J. M. Stevenson reports a somewhat interesting case of angina pectoris, in the Pittsburgh *Med. Jour.* A man, aged 64, temperate and active, after being engaged in active work all morning, ate a full dinner. Immediately afterwards, with a cry of pain, he sank to the floor, struggling and insensible. Brandy and strong aromatic spirits of ammonia failed to elicit any evidence of their irritant properties. After using a variety of remedies, six drops of nitrite of amyl were poured upon a handkerchief and administered very cautiously, allowing an abundance of air. After a few inhalations the face became flushed, pulse increased in frequency and fullness, respiration became quicker, in ten minutes all struggling ceased, and in twenty minutes consciousness returned. Three days subsequently he had a similar attack, which was relieved by the same means, but on the evening of this day he had another, and no one being present to administer the amyl, he died in five minutes. A post-mortem was refused.

Sulphurous Acid in Consumption.

Most readers are aware that sulphurous acid is one of our most important bacillicides, and the more to be recommended, as it can be inhaled with impunity. Mr. Julius Kircher, a pupil of Liebig, and owner of a chemical factory in Brooklyn, writes as follows to the *Zeitsch. f. d. œstr. Apoth. Verein.*

The observation of Koch has found a brilliant confirmation in my factory, where a large quantity of sulphur is evaporated daily. That in this process a great deal of sulphurous acid is formed can easily be imagined. During the forty-four years that my factory has existed none of the many laborers have ever been affected by tubercular consumption, nay, more, frequently enough persons in the beginning stages of this disease applied for admittance and were cured within a few weeks, simply by inhaling the sulphurous acid. If not too far progressed, these individuals become strong, stout, and perfectly healthy again.

All diseases zymotic in character, even cholera, stay away from his factory and those working there. Persons affected with bronchial catarrh are rapidly cured.

Phthisical patients should live in rooms where hourly 1 to 2 drachms of sulphur are evaporated on a warm stove. First eight or ten days there is increased irritation of cough and expectoration; then these cease, and the individual rapidly improves. Convalescents should live for a time in rooms filled with aromatic watery vapors.

Nephrotomy.

In the course of the Presidential address at the last annual meeting of the Yorkshire Branch of the *British Medical Association* (*British Medical Journal*), Dr. T. R. Jessop reported the following interesting case: The patient was a female. Purulent urine was being painfully squirted every few minutes from an intolerant bladder. Nothing more than the single fact of purulent urine could be developed by the most careful physical, microscopical, and chemical examination. The neck of the bladder was dilated, and when the forefinger was swept around the interior of the viscus, the left ureter could be felt in the wall of the bladder, as firm and as prominent as a whip-cord, while the orifice of the right could only with difficulty be made out. The left kidney was exposed in the loin, its substance was incised, and from its pelvis there exuded from two to three ounces of offensive pus, after which an uninterrupted recovery took place.

Acute Heart Lesions in the Very Old.

It is a well-known fact, that acute diseases of the heart, at least, undoubtedly those of an inflammatory character, happen very rarely in the aged. Dr. Ch. Féré (*Revue de Med.*, 1882, *No.* 3) draws attention to a new etiological cause for these lesions. Among 134 autopsies which Féré made during seven months in the Salpêtrière he found seven acute diseases of the heart, peri- and endo-carditis. Of these, in one case the acute pericarditis had appeared as a complication of pleuro pneumonia (in senile persons

a very rare occurrence), and six had happened in consequence of diffused kidney lesions. Two of the latter were the common senile lesions of the kidneys; in the four other cases, however, secondary disease of these organs, besides dilatation of the pelvis of the kidneys and of the ureters, due to obstruction in the urinary passages, were noted. Féré mentions correctly, that these complaints are not common enough to be considered an accidental coincidence with the heart affection.

Local Treatment of Erysipelas.

Dr. Rothe recommends (*Memorabilien*) the application of the following liquid every two hours to the affected parts.

℞. Acid carbolic,		
Alcohol,	āā	1 part
Ol. terebinthinæ,		2 "
Tr. iodinii,		1 "
Glycerinæ,		5 " M.

This mixture causes no pain. Internally, he recommends quinine and digitalis, and an emetic if indicated.

The Cause of Tetanus.

Dr. F. Schuttze reports, in the *Neurol. Centrlbl.*, 1882, No. 6, the microscopical examination of the central nervous system of four cases of traumatic tetanus. In all the cases, nothing was found which would have been characteristic for an acute meningitis or myelitis. Schuttze is with justice opposed to all vague publications of the post-mortem examinations of such cases, and mentions that whatever he had read, so far, of such reports, were simply normal post-mortem appearances, which could be noted in any dead body. The anatomical cause of this dreadful disease continues, therefore, still to be unknown.

A New Anti-Scorbutic.

The *Med. Times and Gaz.* says that "amchur," which is made from green mangoes that have been skinned, stoned, cut into pieces and dried in the sun, has been introduced among the native soldiers in India as an excellent substitute for lime juice in scurvy. It also promotes digestion. One ration should be half an ounce, which would be an equivalent for one ounce of good lime juice.

Vaccinal Micrococci.

The *Lancet* says that M. Straus has plainly demonstrated the presence of the special micrococcus in microscopical preparations of the vaccinal pustule from the calf. He places the excised fragments of skin in absolute alcohol, cuts sections and stains them with methylamine violet, and then discolors them, until only the nuclei, the bacteria and micrococci remain visible. Under a strong magnifying power, the latter were visible, as extremely minute points, tinted blue, about a thousandth part of a millimetre in diameter, and grouped in colonies.

Correspondence.

A Numerous Progeny.

Ed. Med. and Surg. Reporter:—

There is a farmer living in this county, about eighteen miles from this city, who has nine children, the oldest of which is ten and the youngest two years old. I will give their ages, sex, etc.:—

Girl	10 years.
Twins (boy and girl)	8 "
" " "	6 "
Girl	4 "
Triplets (all girls)	2 "

These children are all living and healthy, and the parents are also healthy. Who can beat this?

Maryville, Mo. J. B. Morrison, M.D.

News and Miscellany.

Medicine in England in the Beginning of this Century.

In the course of the Introductory Address delivered at University College, London, Mr. Marcus Beck, in describing the past history of medicine in England, said "At the beginning of this century the profession was divided into distinct grades.

There were, first, the physicians who had, as a rule, received such scientific education as was to be obtained at that time. They had mostly attended lectures at one of the English or Scotch Universities, and spent some time in practical study in a hospital. Then there were the surgeons, licensed by the College of Surgeons, then just founded in its present form. These also had received some education in anatomy and surgery.

Lastly, there were the apothecaries, and to them fell the larger share of medical practice of the time. It was not uncommon, however, for these two last to be joined together in the person of one man, forming the surgeon-apothecary, who was the precursor of the modern general practitioner. The practice of the apothecaries differed from anything we have within the limits of the legitimate medical profession in the present day. They were essentially prescribing druggists, and could legally charge only for the medicine they prescribed. Thus they could receive no remuneration unless they ordered some medicine, and the more they ordered the more they got; a style of practice calculated to inspire a firm belief in the efficacy of drugs. It was not

necessary for the apothecary to receive any medical education beyond being apprenticed to some one already in the trade, and the jurisdiction of the Society of Apothecaries, which necessitated even this amount of training, only extended to a distance of seven miles around London.

The Epidemic of Typhoid Fever in Paris.

The latest information shows that the epidemic has assumed terrifying proportions. On October 22d there were 2175 typhoid fever cases in the hospitals. For the week before, from 25 to 50 patients were daily admitted to the hospitals suffering from this disease. On October 24th twenty-five burials of persons who had succumbed to the disease at their own residences, took place; on the 25th eleven. After October 15th the daily number of admissions to the hospitals ranged from 25 to 77, while from the 9th to the 14th they oscillated between 86 and 180.

At the commencement of the epidemic, the hospital administration was petitioned to create new services, but the work went on with characteristic slowness, although there is a new hospital (l' Hop. Bichat), all ready to receive beds, etc. Finally, when all the chronic cases had been discharged and the already filled wards encumbered with cot-beds, they set about hastily constructing barrack hospitals in the grounds of the Hôp. Cochin, Midi, etc. Even with these new services the hospitals are encumbered and the administration has been again obliged to open the provisory services in the two ancient edifices formerly belonging to the old Hotel Dieu, on the left bank of the Seine.

The hospitals of Paris, notwithstanding their number, prove totally inadequate when any epidemic occurs, and at the best of times are often encumbered with cot-beds.

The Secret of Noble Life.

Mr. Jonathan Hutchinson thus concluded his Introductory Address at the London Hospital: "If now I were to sum up in one sentence what I have been enforcing, it would be this; the secret of all noble life lies in belief, and the characteristic of all noble minds is the vigor with which they believe that which is true. Try to attain belief in the reality of all things; so shall you never want for motives, so shall you be able to live and work without hurry and without sloth. Finally, permit me to commend to you this formula; prize strength, love the beautiful, practice self-denial, and be patient."

Statistics of Suicide in Prussia.

According to details from official sources, which have recently been published in the German press, suicide is on the increase in Prussia, the annual proportion of self-inflicted deaths per 100,000 of population having risen from 13 in 1869, to 18 in 1880. The manner in which these suicides are carried out does not seem to have varied much, with the exception of a greater preponderance of poisoning among the female cases. May, June and July are the months most fatal in this respect. The number of suicides in each period of human life seems to increase with more or less regularity until the stage between fifty and sixty years of age is reached, which shows the highest proportion. There is an excess of deaths shown for the period between twenty and twenty-five years of age; still it does not alter the general fact as to the later portion of middle-age showing the most cases of suicide.

The Health of Providence, R. I.

According to the report of the health authorities there were 47 deaths in Providence for the week ending Nov. 11th, a slight increase on recent weekly averages. The youngest decedent was 4 days, and the oldest 86 years. Typhoid fever caused 10 deaths, which accounted for the total increase. There are about 214 cases of typhoid in the city. The severity of the disease may be judged from the reports of the physicians, which are as follows:—

Disease mild, 49 cases, or 23 per cent. of all. Disease average, 103 cases, or 48 per cent. of all. Disease severe, 62 cases, or 29 per cent. of all. Disease malignant, no cases. Total, 214 cases.

In the first week less than six per cent. of the cases were reported as "mild," in the last week more than 28 per cent. were so reported. The outbreak is very sudden and very severe, but probably very transient, and what is somewhat peculiar, is spread throughout the city and not confined to any one locality.

Certificates in Sanitary Science

The College of Physicians in Ireland has recently made arrangements for granting certificates in Sanitary Science. Stated examinations will be held in January, April, July, and October. Every candidate must be a Licentiate in Medicine, of the College, and must lodge a fee of five guineas, which will not be returned in case of rejection. The examination will comprise the following subjects: 1. Engineering, including hospital and house construction, sewage, drainage, ventilation, and water-supply. 2. Law; the Acts relating to Public Health; duties of health officers. 3. Etiology and prevention of disease; epidemiology, contagion, infection, hereditary influence, accommodation and conveyance of the sick, and the management of hospitals. 4. Chemistry; air, water and food. 5. Meteorology and climatology; vital statistics. The candidate will also be examined in the analytical chemistry of air, water and food.

Vinegar for the Sick Room.

The Boston *Journal of Chemistry* says:—There is a French legend that, during the plague at Marseilles, a band of robbers plundered the dying and the dead without injury to themselves. They were imprisoned, tried and condemned to die, but were pardoned on condition of disclosing the secret whereby they could ransack houses infected with the terrible scourge. They gave the following recipe, which makes a delicious

and refreshing wash for the sick-room: Take of rosemary, wormwood, lavender, rue, sage and mint, a large handful of each. Place in a stone jar and turn over it one gallon of strong cider vinegar; cover closely and keep near the fire for four days, then strain and add one ounce of powdered camphor gum. Bottle and keep tightly corked. It is very aromatic, cooling and refreshing in the sick-room, and is of great value to nurses.

Philadelphia County Medical Society Lectures.

A course of lectures by Prof. Austin Flint, Senior, of New York, on "The Physical Exploration of the Lungs by means of Auscultation and Percussion," will be given in the hall of the Society, N. E. Cor. Thirteenth and Locust streets, on Saturday, November 25th, December 16th and January 13th, at 8 P. M.

Lecture I.—The True Mode of Study and its Requirements as Regards Auscultation and Percussion. The Signs Obtained by Percussion.

Lecture II.—Auscultation and the Respiratory Murmur, with its Abnormal Modifications.

Lecture III.—The Râles and the Vocal Signs.

Com. on Lectures { JOHN B. ROBERTS, *Ch'n.*; CHAS. H. THOMAS; WM. S. LITTLE; M. S. FRENCH; EDWARD T. BRUEN.

The Athletic Association of the University of Pennsylvania.

The old University, ever foremost in all true progress, has determined to make a new departure. We have received a circular from a committee, who have in hand the organization of an Athletic Association, which shall comprise five departments: Boating, Foot-ball, Base-ball, Cricket and Athletics. There is no entrance fee, and the annual dues will be three dollars. It is proposed to lay out a running track, cricket, tennis, base-ball and foot-ball grounds, and build a gymnasium on the University grounds. To all who realize the importance of a *sound body* as the habitat of a *sound mind*, this proposed improvement will heartily commend itself. Any one desiring further particulars can address any of the committee, consisting of J. William White, M.D., H. Laussat Geyelin, Thos. G. Hunter.

The Veterinary College of the University of Pennsylvania.

A subscription of $10,000 has been received by the University of Pennsylvania, for the establishment of a veterinary college. Several physicians of reputation and ability are now in Europe, pursuing special courses of study to qualify them to fill professorial chairs in this new college.

Lebanon County Medical Society.

Dr. Carl Seiler, of this city, will deliver a lecture before the Lebanon County Medical Society, on the first Tuesday in December. His subject will be "Nasal Catarrh; Its Pathology and Treatment." The lecture will be illustrated by drawings, and patients will be operated upon.

Two Cases of Poisoning from Whisky.

The Glasgow correspondent of the *Lancet*, writes as follows: Two cases of poisoning from whisky drinking have been noted in our daily papers during the past week. One man had been drinking in a public-house till a late hour, and on going home he procured a further supply of liquor; shortly afterwards he fell asleep, and in a few hours fell from his chair, dead. The other case was that of a man who, in drunken bravado, agreed to drink a whole bottle of whisky "without taking it from his head," and did so, with the result that he soon became comatose, and had to be removed to the Infirmary.

Proposed Sanitary Museum in Sunderland.

A praiseworthy attempt is about to be made in Sunderland to extend the knowledge of sanitary matters among the residents in the North of England. The effort is initiated by Dr. Mordey Douglas, senior physician to the Sunderland Hospital for Sick Children, who proposes that the new municipal buildings be made to include accommodation for a permanent exhibition or Sanitary Museum, in connection with which lectures on health subjects may be delivered from time to time, the discourses to be illustrated by the various exhibits. The proposal is a good one and worthy of successful realization.

Public Nuisances.

At a recent meeting of the Board of Health of this city, nuisances were reported as existing at several points. A row of unfinished buildings were said to be unsafe, and water in the cellars emits a disagreeable smell. The Medical Inspector will make an examination.

We frequently see such reports and statements in the daily papers. We must say most emphatically that the public health imperatively demands that such nuisances should not be tolerated an hour.

The Commencement of Scientific Medical Education in England.

According to the Introductory Address of Mr. Marcus Beck, at University College, London, that institution, then called London University, was founded in 1826, and for the first time a systematic scientific education was given in London, on essentially the same lines as are followed to the present day.

Carlyle's Patience.

In his Introductory Address at the London Hospital, Mr. Jonathan Hutchinson, speaking of Carlyle, said: "He had not learned what we may, I think, without irreverence, style the Religion of Patience. By patience I mean not the mere passive virtue of endurance, which, indeed, is not unfrequently no virtue; I mean rather the ability, when we have done our best, under all possible circumstances, to rest undespairingly and trustfully for the result."

Poisoned by Mistake.

Up in Ontario, a short time ago, a man and his two daughters took some "herb tea," to relieve colds. They were all taken violently sick and died. It is supposed that deadly nightshade was among the herbs. We desire to say, in most emphatic terms, that he who attempts to meddle with drugs about which he knows nothing, is playing with fire, and can only be characterized as a very foolish person.

Unwitting Suicides.

This time it comes from New York. A man and wife *blow* out the gas in a room in a hotel, and the next morning are found dead. Thorough ventilation of rooms, active and intelligent night watchmen, and a general watchfulness over the guests of a hotel, might do much toward preventing these catastrophes, which are becoming altogether too frequent.

The Health of the Jeannette Arctic Exploring Expedition.

Lieutenant John W. Danenhower says that during all the time the Jeannette was imprisoned in the ice, the health of the crew was excellent. They were away from civilization of all kinds, floating about or imprisoned in the ice, for twenty-eight months, and not a single case of scurvy occurred. The expedition was a temperance one.

Unobstructed Drainage.

The City Solicitor of Philadelphia has rendered an opinion, in which he holds that the city is obliged to dredge docks into which the city sewers empty. This is a very important decision, since a free and untrammeled outlet for all sewerage is one of the prime essentials of a healthy city. Such action should be made compulsory upon the authorities of all cities draining into rivers.

Degrees of the University of Pennsylvania Open to Women.

At a special meeting of the Board of Trustees of the University of Pennsylvania held November 14, it was resolved that any of the degrees or honors of the University could be conferred upon women who shall pass the proper examinations.

Items.

—Hildebrandt, the eminent teacher of gynæcology, in Koningsberg, is dead.

—Duncan Campbell, M.D., a member of the Local Government Board, of Nova Scotia, died Nov. 15th in Port Hood.

—Dr. J. S. Mohr was found dead in his office in Chicago, Nov. 15th. He had apparently been dead for several days, but there were no marks of violence upon his person.

—On Nov. 15th, the Board of Health issued a proclamation declaring the epidemic of yellow fever in Pensacola at an end, but advising absentees to keep away a little while longer.

—An ordinance relating to the prevention of the spread of infectious diseases, was favorably reported by the Law Committee of Councils of this city, on November 15th.

—The Camden County Medical Society, on Tuesday, Nov. 14th, appointed the following committees: On Medicine, Doctors Snowdon, Mulford, Smith; Surgery, Benjamin, Gross and Blake; Obstetrics, Mecray, W. A. Davis, Jennings; Microscopy and Pathology, Ridge, Henry, Shivers, Hamilton; Medical Jurisprudence, Garrison, Ireland, Iszard; Nervous Diseases, Armstrong, Stout and Young.

—The officers of the American Public Health Association for the ensuing year are: President, Dr. Ezra M. Hunt, New Jersey; First Vice-president, Dr. Albert L. Gihon, U. S. N.; Second Vice-president, Dr. J. E. Reeves, Wheeling, W. Va.; Treasurer, Dr. J. B. Linsley, Nashville, Tenn.; Executive Committee, Dr. Thomas L. Neal, of Onio; T. J. Turner, of the U. S. Navy; G. P. Conn, of New Hampshire; J. F. Billings, of the U. S. Army; J. J. Speed, of Louisville, and H. D. Frazer, of South Carolina.

OBITUARY NOTICE.

DR. SAMUEL WHITE THAYER,

A distinguished physician and one of the most eminent citizens of Vermont, died in Burlington, Nov. 14th, after a long illness, of blood poisoning, aged sixty-five. During the war he was surgeon-general of the staff of the Governor of Vermont, and established and organized three military hospitals. He leaves a widow and one son, Dr. Charles P. Thayer, of Boston.

QUERIES AND REPLIES.

A. O. S., Pa.—"Infarction" means a stuffing or blocking up.

V. W. J.—We would suggest measures looking to the relief of the dyspepsia, to overcome the constipation; producing daily free evacuations, as well as friction and support to the abdominal walls, until they regain their tonicity.

MARRIAGES.

COLLINS—LA TOURRETTE.—At Fort Union, on Thursday Oct. 5th, 1882, by the Rev. Jas. A. M. La Tourrette, Post Chaplain U. S. A., assisted by the Right Rev. Bishop Dunlop, of New Mexico, Genevieve, daughter of the officiating Presbyter, and Dr. Joseph H. Collins, A. A. Surgeon, U. S. A.

GRIFFITH—JENKS.—In the Woodlands Presbyterian church, Philadelphia, October 5th, by Rev. Dr. Benjamin Griffith, assisted by Rev. Dr. Crowell, Dr. J. P. Crozer Griffith, and Julia E., youngest daughter of Barton H. Jenks, all of Philadelphia.

DEATHS.

BENNETT.—Suddenly, at his residence, in Danbury, Conn., Oct. 27th, Ezra P. Bennett, M.D., aged 76.

BOND.—In this city, Oct. 26th James Bond, M.D., in the eighty-third year of his age.

COMLY.—In this city, Oct. 28th, Dr. Isaac Comly, in the 73d year of his age.

HOWELL.—In Woodbury, N. J., October 10th, Benjamin Howell, M.D., in the seventy fourth year of his age.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

CENTRAL AMERICAN MEDICAL CURIOSITIES.

BY FERD. C. VALENTINE, M.D.,
Of New York.

(*Continued from page* 400.)

Common wax is used internally as an antacid, emollient and laxative. The dose is unspecified. "Yellow ointment," which is employed to stimulate granulations in chronic ulcers, is composed of six parts of wax, twelve of turpentine, and sixteen of lard. These are melted together, strained through a cloth, and while still hot the yolk of an egg is stirred into the mass.

Cypress wood is considered sudorific, diuretic and astringent, the latter quality being also attributed to the fruit. Wild plums are frequently used in place of tamarinds, by persons whose "intestines are torpid," and much benefit is claimed to have been derived from their use in putrid dysentery. Those affected with itch rub the diseased parts with the leaves, to obtain relief from the itching and burning. The gum is used as is gum acacia.

The cocoanut offers its milk as an agreeable refrigerant, especially before ripening, and it is recommended in affections of the bladder and active uterine hemorrhage. The "hair" of the ripe cocoa is boiled in water and the decoction strained and given to patients with chronic uterine flow.

The flesh of the nut is ground up with water and given as an expectorant. Inasmuch as green cocoanuts are always obtainable in Central America, I have known only foreigners to assault their stomachs with the ripe flesh.

The leaves of the wild borage (Borago Sylvestris) are boiled, in the proportion of an ounce to three pints of water, and given in "side-ache" (pleuritis?) rheumatism, smallpox and measles.

Cabbage juice mixed with bread crumbs makes a poultice which is applied to the forehead and temples, to cure headaches.

Cumin seeds "are the most efficacious remedy for ventosities of the stomach." They also excite the sexual appetite, and are useful in tenesmus, when this symptom is not connected with bloody alvine discharges.

Contrayerba (several species of dorstenia) excites perspiration, comforts the heart (*i. e.*, is a sedative), and is an antidote to coagulating poisons, to malignant fevers, to worms, and to snake poison. A half teaspoonful of the powder is given in divided doses through the day.

Copalchi bark, in infusion, is extensively used as an anti-periodic, to cure acidity of the stomach and in slow digestion. It is highly praised as a remedy in hydrothorax, yet those who would use it are warned that it will do harm, and even produce dysentery, in cases where the stomach or liver is inflamed. The bark is chewed, to preserve the teeth. Splenitis is treated by wearing a plaster on the abdomen, composed of a combination of equal parts of powdered copalchi and soap, to which enough lard is added to make it easily extensible upon a cloth.

The juice of the coyol, a fruit somewhat like the tamarind, is said to be aphrodisiac, stimulant and diuretic. It is used to stimulate the

menstrual flow, to cure sterility in females, and to purify the blood. It is reprobated in cases affected with any disease of the thorax.

The leaves of crespillo or cabello de ángel (angel's hair), an agaric, are ground and applied over parts which it is desired to blister. Inasmuch as the deep burn produced is never followed by urinary trouble, the plant may be worth investigating. As a blister, however, it is not entirely reliable, inasmuch as in the crude manner it is used its time of action is extremely variable.

Deer horns are recommended in jaundice, intestinal worms, fevers, melancholia, nervous affections in general, and dysentery. The ash of burnt horns, two tablespoonfuls in rice water, twice a day, is used as a sudorific, to limit hemorrhages of all kinds, and as an antacid. In other affections the deer horn filings, one ounce, are added to a quart of water, boiled down to a pint, which is the daily dose.

Culantrillo (*Adiantum capillus veneris*, L.) in infusion, is given to parturient women, to abbreviate the enforced marital separation.

Coriander seeds are employed as carminatives, and to correct foul breath. Worn in a bag, near the throat, they are regarded as an amulet against all contagious diseases. A patient who consulted me for gonorrhœa, said that the prostitute who infected him must have been "very poisonous," because she had succeeded in overcoming the power of his bag of coriander, tied to a string around his neck.

All snakes are presumed to possess curative virtues, but I know only of three kinds being used. The masacuate (chicken snake) is eaten by all, and especially recommended to convalescents. Powdered toasted rattlesnakes, in half teaspoonful doses three to four times a day, are recommended in low fevers, syphilis and skin diseases. A soup made of this snake is used for the same purpose.

Atrophied and contracted limbs are rubbed with the fat of the boba, a small snake, said to be very venomous.

Infusion of peach leaves (1½ oz. to 8 ozs. of water, boiled down one-half), is recommended as a mild purgative and vermicide. The adult dose of this infusion is four ounces during the day.

The moss which grows on oak-bark is recommended for whooping-cough. Acorn tea is "buen remedio" for all forms of phthisis, and an orgeat made of ground acorns is beneficial to those "whose cough is accompanied by a throwing out of blood."

The powdered fruit and gum of the espino blanco (cratœgus oxycantha), enjoy the reputation of healing ulcers on the genitals and in the mouth, locally applied, while a soup made of the root is an infallible remedy for snake-bites. The patient is bathed in the soup, and given large doses of the same. The same soup is also beneficial in chronic coughs. The cimaba cedron is extensively used as an antiperiodic and an antidote to the bites of venomous snakes and rabid animals. I have used it as an antiperiodic in a large number of cases, and always with satisfactory results. I cannot, however, testify to its efficacy in pernicious fevers, as I have never been so placed that quinia was not at hand, and did not believe myself justified in experimenting where life was in danger. Those who may desire to test the usefulness of this drug can easily obtain samples of an excellent and reliable solid and fluid extract by addressing "Licenciado Eduardo Bendfeldt, Escuintla, Republica de Guatemala, Centro America."

"Friega-plato" is a plant, the botanical classification and the virtues of which I have not attempted to investigate, as it is claimed to infallibly cure syphilis, *even in poultry*. I am not only willing, but anxious to learn all that may help me to relieve the affection with which I have been most thrown in contact, and I pride myself that I have not treated a patient who has not enjoyed my fullest sympathy, yet I must confess that when hens act disreputably, I am not humanitarian enough to desire to relieve their sufferings otherwise than by instant death. "Friega-plato" I heard of through cases which came to me for treatment, and who had invariably used it ineffectually.

The actual cautery is used in snake bites, in malignant pustules, fungoid granulations and chronic ulcers. Broad pieces of iron and steel are also used for blistering, by heating them and holding them over the part affected until a large vesicle is produced.

The chick-pea (cicer arietinum), in decoction, is recommended as a vermicide, a diuretic, in gravel and stone.

Beeves' foot jelly is given convalescents, and is asserted to cure chronic metrorrhagias and fevers which are dependent upon debility.

Ginger, which grows wild in nearly all parts of Central America, and is almost invariably excellent, is recommended as a general tonic and to cure dropsies. In pleurisy, it is used externally, the powdered root being mixed with equal parts of black pepper, and made of the consistency of a plaster by adding albumen. It is then extended on a cloth and applied to the painful part.

Cochineal is said to be astringent, sedative (especially in children's coughs), diaphoretic and antiperiodic. It is also recommended in dysentery and threatened abortion. It is ground with equal parts of sugar, and 20 to 40 grains of the powder are given with simple or acidulated water.

Infusions of the flower, fruit and bark of the pomegranate are recommended in diarrhœas and leucorrhœas, and the derma of the fruit is powdered and given in twenty-four grain doses thrice daily, as an antiperiodic.

As a vermicide, it is used with frequent success as follows: Two ounces of the fresh epidermis of the pomegranate root are scraped into eighteen ounces of water. This is boiled down to twelve ounces, and eight tablespoonfuls are given every half hour, fasting.

A very complete account of the use of guaco in Central America is found on page 1659 of the U. S. Dispensatory, 1878. To this I would add that those who go into parts where snakes are said to abound, daily drink an ounce or two of the juice expressed from the guaco leaves, and anoint their bodies with the same, claiming to thus enjoy immunity. It has also been used in the same way as a prophylactic against cholera.

Ox bile is considered a tonic for persons afflicted with any of the dyspepsias, and is said to cure jaundice. In either case twelve grains, partly dried in the sun and mixed with an equal quantity of soap, is made into pills and taken during the day.

It is dissolved in warm water and injected into the auditory canal, in suppurative otitis, "when the pus is yellow."

Iron filings are used in all possible affections, but are particularly recommended in dropsies, amenorrhœa, anæmia, hysteria, sterility, leucorrhœas and splenitis.

The filings are given in six-grain doses, mixed with sugar, twice daily, as a rule, and they are first exposed to the sun and dews on a white plate, for eight continuous days. They are then triturated with sugar and given as above detailed.

Castor oil, besides its usual employment, is praised as relieving the headache incidental to acute catarrhs, if a bandage is anointed with it and worn about the head for several days. A poultice is made of the beans, ground and mixed with oil, and is tied over the region of the spleen, to cure inflammation of this viscus.

All parts of the hypericum perforatum are used in infusion, one-quarter of an ounce of the chopped plant to each dose in hysteria, hypochondria, rheumatism and hæmoptysis.

Soot is given in drachm doses, in coffee, as a vermicide, and is beaten up with albumen and thus used in herpes and tinea.

Ants of all kinds are famed for their curative properties in impotency, apoplexy and dysuria, and to relieve paralyses. In the latter affection, they are crushed and applied as a poultice to the affected part. The sexual organs are said to receive additional vigor from being frequently rubbed with ant-oil, which is made by endeavoring to drown four ounces of ants in two ounces of any oil, sealing the bottle, and after exposure to the sun for twenty successive days, straining.

The "Spirit of ants," as it is called, is made by catching half a pound of ants during the "increasing quarter of the moon," in June or July, and soaking them for eight days, in twelve ounces of strong aguardiente, during which time they must be exposed to the solar rays from sunrise to sunset, and shaken every hour. The "spirit" is then filtered and given in 40 to 50 drop doses daily.

Eggs. The albumen mixed with water, with or without sugar, is prescribed in dysentery and in "biliousness." The ground shells are prescribed in about half drachm doses, twice a day, in pyrosis.

Goitre is very frequently seen in the mountainous districts of Central America, and I have known patients to anoint their bronchocele for months with a salve composed of two parts of eggs and one of fresh lard, without any benefit, of course. Yet they persist, notwithstanding their failure, and lay the flattering unction to their souls (and goitres) that they are doing the proper traditional thing.

The delicious flesh of the iguana (*I. tuberculata*, also called guana, huana, iguano and iguanha) is recommended in syphilis, especially in secondary eruptions. It is yet more highly lauded in cancer. Professionally, I have not used it, but unprofessionally have frequently eaten it, and consequently can recommend it to all as being far more delicious than frog's legs.

Magnetized iron is said to have relieved headaches, toothaches, and rheumatisms, by being passed over the painful parts.

Several species of gourds, called jicaros, are used in medicine. The rind is boiled, or the seeds emulsified, and the juice made into a sort of electuary. For all of these anti-syphilitic virtues are claimed. I have used them as expectorants, in those regions where drugs were few; I almost said "fortunately few."

The newt or Eft (Sp. lagartija), like nearly all of the lizards, is praised as a remedy in cancer, syphilis and skin diseases. Buboes are treated

by opening the thorax and abdomen of the lagartija and fastening it over the swollen gland, to die there. The skin, removed with the fat, is applied, while fresh, upon parts where foreign bodies have penetrated the skin.

Milk, as an aliment, is considered to produce intermittents, stupidity, sadness, indigestion, diarrhœa and constipation.

As a remedy, milk is used in poultices and fomentations, in preference to water ; it is given by the mouth and rectum in dysenteries and diarrhœas, in the latter with lime-water.

Whey "refreshes and softens the abdomen," therefore it is very useful in hot fevers, scurvy, epilepsy, insanity, and cancer of the breasts." In dysentery it is administered with manna, with tamarinds in bilious fevers, with alum in hemorrhages, with sulphur in itch and hemorrhoids, and warts wetted with whey are said to be cured.

Fresh cream is used in burns, scalds, and as a dressing to parts that have been blistered. It is usually applied on young plantain or banana leaves.

Goats' milk "does not cause sadness," and is frequently given to children and convalescents.

Mares' and asses' milk are much used by debilitated persons, and in extreme cases human milk is employed. The juice of lettuce, strained and given in three to six tablespoonful doses, is used as a sedative, but not with constant effect.

Lye of wood-ashes is employed in the bites of venomous reptiles and rabid animals, and the stings of insects. In scaly skin diseases, fissures of the skin and callosities, lye is used locally, while sarsaparilla, generally in decoction, is given, and the patient abstains from the use of pork, acid foods and spices.

That species of mistletoe which grows about orange-trees is praised as a remedy for epilepsy and nervous affections in general. It is dried and powdered, to be given in drachm doses twice daily.

Sweet limes, which to the foreigner taste like juicy, flavorless oranges, are much used in pyrosis, ardor urinæ, and in injections in colics. In "earache" some drops of sweet lime juice are instilled into the auditory canal, which is afterwards plugged with cotton.

It is considered a "cold remedy," consequently is prescribed in all affections concomitant with heat, whether atmospheric or personal.

Limes (*Citrus acris Miller*), of a most exquisite flavor, abound in nearly all parts of Central America, while the lemon is comparatively rare. As far as the range of pathology goes, the lime-juice is used both locally and internally. Its most frequent employment is in alopecia, affections of the eye—imagine lime juice squirted upon an inflamed conjunctiva!—scurvy, jaundice, and with wine in putrid fevers, cholera and all asthenic affections. An infusion of the bark and seeds is given as a stomachic and carminative.

In gastritis and enteritis, lime-ade with gum arabic is given, warm, in ounce doses, every two or three hours.

Slices of limes are tied upon the umbilicus in dysuria, and are similarly used upon buboes, but for this affection they are toasted before being applied.

Lime-juice, mixed with wood-ashes, is rubbed upon inflamed joints.

After the Indians remove the jigger (nigua, chigoe, chique, sarco psylla penetrans) from their feet, they instill a few drops of lime-juice into the space left, and then fill it up with cigar or cigarette ashes. Whenever I performed this little operation upon myself, I omitted the lime-juice.

(*To be Concluded.*)

CLINICAL STUDY OF INEBRIETY—RATIONAL METHODS OF TREATMENT.

BY T. D. CROTHERS, M.D.,
Superintendent Walnut Lodge, Hartford, Conn.

The aim of all treatment is to build up healthy functional action of the mind and body. This will not follow from the applications of medical means alone, nor the absolute restraint of locks and bars, or by appeals to the will and emotional faculties.

Rational treatment for inebriates is simply rational means to meet diseased action along the line of laws and by the use of forces which may be understood. Take the question of the honor of the patient under treatment, his word or promise that he will not take spirits when he is exposed to temptation.

One class of observers are confident that the best results can only come from a full coöperation of the patient, and by placing him on his honor, thus stimulating the will to guide and restrain the diseased impulses. Other persons equally competent deny the value of such means, and under no conditions and circumstances depend on the honor or will of the patient, but insist that his will is injured by stimulating it in this way. Yet as a rule all patients are clamorous, after a few weeks' treatment, to be trusted, as if they would like to see how far they could go and not fall.

In many cases the nervous paroxysm previously mentioned takes this form of excitement, insisting that restraint indicates want of confidence, hence depression, wounded pride and ambition to help themselves and self-confidence to go alone, etc. Both of these views come from a limited knowledge of the whole subject, and both are therapeutically true in practice. In insanity, the will power or honor of the patients are rarely considered as a factor in the treatment, but in inebriety it is all important to take into consideration this element, and how far it influences the organism. Inebriety cannot be measured by the same standards of treatment that other disorders of the nervous system are, for the reason that it is a disease "on the border land," with a large physical element entering into every phase of its progress.

In many cases, after a few weeks' treatment, an irritative depression follows, from the application of restraint, which may not only provoke periods of nervous agitation, but counteract much of the good accomplished by other means.

When this continues for some time, a low form of delirium, with delusions, is apt to follow. The patient will intrigue to procure spirits, and have no ambition to aid or help the work of the physicians for himself and others. He will display a compound of reckless abandonment and mental feebleness, that seems beyond the reach of medicines. The treatment in such cases is of little value; after a few months he is discharged, and relapses at once, reporting the most willful falsehoods of the asylum work and its principles. This irritative depression in some cases never passes away entirely while under restraint, and may be a hint of continuous craving for spirits. Or it may be the result of continuous restraint and want of confidence in the patient's strength to help himself, or the absence of means applied to rouse up the will to greater exertions to aid the physician. If at the beginning of this condition the restraint is modified at certain times of the day, when the danger was least, as, for instance, for a few hours after each meal, it might disappear at once. The restraint in many cases should be varied; when in certain conditions the patient shows depressing excitement, he should be sent out on some errand or duty in which a certain dependence is placed on his honor to return at the time mentioned. This duty should be in the least exposed places, and one that demands exactness and punctuality.

This cannot be strictly called trusting to the honor of the patient, because it is coupled with some duty and work. The mind is not free to follow its own dictates, but is free to carry out the will of another. The application of restraint and trusting to the will of the patient may be illustrated in some cases from the daily records of the asylum.

Case 1 became very restless and excited at the absolute restraint which was continued many weeks after admission. This state developed into a low, nervous melancholy, which disappeared soon after he was given the daily task of procuring milk for the house, a mile away. The liberty and duty of this work was a constant tonic to his mind.

Case 2 showed marked signs of nervous irritation and exhaustion, suffering from frequent recurring paroxysms of restlessness, which passed away when he was sent on an errand with a carriage, daily, to the depot.

Case 3 was like the above, who was benefited by placing another patient under his care, for a walk about the country.

Case 4 at times was sent to the city on real and imaginary errands, with great benefit.

Case 5 was a dypsomaniac, and after the paroxysm, was given liberty to go and come at certain hours, and required to be exact and punctual. On the approach of the paroxysm he gave up to the restraint, and requested to be particularly cared for when the feeling had passed, and he went about as before.

Case 6 was a chronic of many years' duration, who at certain times, governed by his general physical condition, was trusted to go to the city on business. Within an hour after his return he sometimes became restless and needed positive restraint. The application of restraint and liberty alternately was followed by the best results, and finally a cure.

In these and other cases the value of liberty or modified restraint was governed by the condition of the patient and his apparent capacity to control himself.

This can be ascertained after some study and acquaintance with the patient, and is revealed by certain almost indescribable signs and symptoms, which are more or less certain and rarely misunderstood. The aim of the physician is to hold the patient and govern his surroundings with restraint enough to keep him from danger, and at the same time have his full coöperation and confidence. If this restraint is arbitrary, and not adjusted to the conditions of the case, it is irritating and damaging to the nervous system of the patient. At times it is stimulating and then it is depressing and injurious.

These are the cases that in a few instances do well by simply trusting to their honor or word that they will stop the use of spirits. It will be found that they are nearly all inebriates in which the use of alcohol was only a secondary exciting cause, and that some other morbid condition of body and mind provoked the use of alcohol.

In an asylum these conditions and actual causes are in a measure removed. Hence the little danger from the secondary cause, alcohol. In a certain case, where digestive troubles brought on the inebriety, the patient never drank, and was free from all danger of relapse as long as the stomach did its work properly. The moment an attack of indigestion came on he would give way to the least temptation. In another case, a man whose domestic relations are unpleasant will come to the asylum, and go about with full liberty in a day or so, and remain months perfectly sober, although frequently exposed to temptation. In three or four days after his return home he will relapse and make great exertions to procure spirits. Here the exciting cause was probably exhaustion, from mental irritation, from domestic trouble, which reacted in a desire for spirits.

There is another class who constantly relapse, under all circumstances, and who have no honor or pride that can be reached by trust. To them nothing but constant, sharp restraint is recogn zed as an effectual treatment. As a class they will be found inheriting a well-defined insane, and often an epileptic neurosis. Of defective brain and nerve power, they are usually chronic cases, of many years duration. They are among the repeaters who appear at all the asylums in the country, and relapse after all treatment, from the slightest occasion. They always manifest delusions of strength, and at the asylum are full of intrigue, and violate all confidence, relapsing with every chance. To them nothing but military discipline, that is exact and positive, is effectual. They must have removal from all exciting and predisposing influences, and every surrounding replaced by conditions of duty that is absolute. For instance, rules regulating their daily habits of life, medicines and other treatment to be given at different times, and all their work, and every event, regulated with mathematical precision; nothing trusted to their will. Such cases in the asylum, under a firm, sharp control, give way quickly and feel the stimulus of the place and management as a bracing tonic, which, if continued long enough is an important factor in their permanent recovery. These cases sometimes are benefited by the discipline of sea service, or roused up to make greater exertions by some enforced duty. Like all other cases, they are much exhausted, needing rest, building up, with the vigorous mental tonics. The following cases will exhibit some of the usual methods and results which follow from their treatment in asylums.

Case 1, with a marked inebriate inheritance, drank from puberty up to forty-five years of age. At this time he came to the asylum, and after several trials and relapses he was placed on a military system, which grew more rigid as he failed to meet its requirements. Under this he made a rapid recovery, and one year after went into the country house of his brother, who was very exact and positive in his requirements, and to-day is yet temperate and well. He has learned exact habits of life, and fully realizes their value in his case.

Case 2 was a chronic case, dating from a physical origin. He was with much difficulty kept under discipline, and relapsed with every opportunity, but was more easily managed in a semi-military system. He obeyed promptly all requirements when they were urged upon him, and had no disposition to vary as long as the laws and rules were strict. A few months after he went to work on a salary, but could never be trusted to go and come from the office to his home unless with some one.

Case 3 was a secret inebriate with a marked inheritance of insanity, who lived a double life of assumed temperance, but drank constantly in secret. At the asylum he apparently was the most anxious to recover, yet all the time resorted to every method to procure spirits. Every restraint was cheerfully accepted, and every liberty observed with outward care, and yet he always was ready to relapse with every chance. Finally he was placed under the most absolute restraint and watching; he changed at once, and was greatly improved. From this time nothing but the force of restraint that was thorough commanded his respect. If he brought in spirits he expected to suffer for it, and would do it again unless he was under sharp restraint. He seemed to need some combative force outside of his will to resist the use of spirits. These cases are generally incurables, or incapable of self control, and, like soldiers in an army, may be valuable to execute the will of another, and, under certain conditions, carry out a plan of treatment which will result in their temporary benefit.

No matter what the exciting or predisposing influences may have been, the treatment must be

based on restraint that is absolute and does not recognize the power of the patient to help himself. There seems to be a general enfeeblement, amounting almost to paralysis of the controlling power of the brain, which nothing but the will of another can direct or stimulate. The application of restraint for these two classes varies widely, and must depend on the character of the patient and the form of inebriety. In the absence of proper classification and knowledge of these cases they are treated alike, either trusting to their honor to a certain extent, or placing them well under absolute restraint, and the results are unsatisfactory. The superintendents of insane asylums who have a ward for this class, and treat them by absolute restraint, as the insane are, manifest surprise to find that many of them relapse as soon as released, and hence conclude that they are more vicious than diseased. They never realize that their treatment of these cases has been injurious and served to continue the very conditions which it sought to obviate. On the other hand, those who rely on the honor of the patient are continually amazed that so many cases relapse on every occasion, and seem to have no control over themselves. From this they conclude that nothing but supernatural means, from prayer or conversion, can avail, or that they are incorrigibly wicked, and must be punished in jails and prisons. The conclusion from the facts is, that a careful study of each case will point out the degree of restraint and liberty necessary to rouse up the organism to healthy activity. Also, that an asylum should be prepared to apply to each case the degree and form of restraint required, in surroundings that will be effectual. Not unfrequently a class of patients are seen who have a strong tinge of insanity. They are wildly delirious when intoxicated, and are always possessed of positive delusions. They are often kleptomaniacs, and generally more noted for their nerve instability and uncertain mental action. The treatment of this class presents many problems that turn on a thorough acquaintance with the history and nature of the case. Absolute rest and freedom from change are required in such cases, in addition to active medication, of which baths, the electric current, bitter tonics, are most valuable. They are made worse by excitement or appeals to their pride or honor. A private asylum is often the best place, for the reason that more positive quiet and rest can be had; also in many cases the active causes which are not forms of alcohol, can be removed more positively. These cases are most frequently inebriates because of some almost accidental physical condition, which gives the organism a direction towards inebriety. When crime is committed by this class, punishment in jails is always fatal, in the sense of precipitating them into more incurable conditions, or developing some form of insanity from which recovery is doubtful. In asylums the results of treatment are generally promising, but final cure depends on years of quietness and medical care under the direction of another. They are on that mysterious border land that divides sanity from insanity, where all human actions and judgments are uncertain. Often they are mere victims of the surroundings and conditions of living that change with these influences. In many cases marked intellectual disturbances precede the use of alcohol, and inebriety is the result of these defects. For instance, a hypochondriac will reason that alcohol contains some food element needed in the body, and as the natural consequences of his experiment, he is soon an inebriate. At the asylum the treatment must have special reference to these mental changes. Peculiar mental conditions may appear after inebriety has come on, and in the treatment must be recognized and studied. As an instance, a patient has intense egotism and confidence in his ability to perform things that are almost impossible. He reasons keenly that his inebriety is the result of some special physical condition which can be readily removed.

In the treatment an advisory control is assumed, and only absolute restraint is exercised when essential. Great care is necessary to make the methods of using remedies impressive and exact, and to magnify their importance and the results to be accomplished on the patient's mind.

Delusions of persecution are common, and although less pronounced than in the insane, have an important bearing on the progress of the case. Dietetic delusions are also common, and persistent.

The impulses to overeat or to use some one article of food to satiety, are common. The inordinate thirst at times, like a form of mania, takes possession of the mind; all these are factors, whose removal and care requires the attention of physicians.

The success of all treatment depends on a knowledge of the mental and physical conditions present, and the administration of remedies and measures which will meet and break up these conditions.

—Dr. Dorin has just died, at Châlons-sur-Marne, nearly ninety-four years old.

A PAINFUL SCAR REMOVED FROM A THIGH-STUMP, AND ITS SITE COVERED BY A TRANSPLANTED FLAP.

BY J. S. WIGHT, M.D.,

Professor of Operative and Clinical Surgery at the Long Island College Hospital.

A. L. Gagnon, M.D., of Massena, N. Y., in active professional business, married, and forty-five years of age, on the evening of the 25th of August, 1879, was kicked on the calf of his left leg, by a vicious horse, so that there was a compound comminuted fracture of both bones of the leg. An effort to save the limb failed; gangrene supervened about the seventh day after the injury. The leg was amputated on the 2d of September, about five inches below the knee joint. The ligature on the anterior tibial artery included the accompanying nerve, and was removed about ten months after the amputation. The posterior flap sloughed, but in about six months healed up, leaving a large scar. In the meantime, pieces of dead bone came out.

On 16th of November, 1880, the limb was amputated again. An anterior flap, four inches long, was made; there was no posterior flap made; and the extremities of the condyles were cut off, leaving on the inside of the stump a sharp prominence of bone. The operation was performed after the method of Carden. There was severe hemorrhage during the night, and the next morning there was great tension on the stitches, so much so that they were cutting their way out. The flaps were opened, when it was found that the blood came from the articular arteries. The posterior tegumentary tissues retracted very much, leaving a large space to heal by granulation; union was not complete till the next June, some seven months after the amputation; during all this time the pain was severe and constant. But after the amputation wound healed up, the pain was severer than before, requiring large doses of morphine for its alleviation. In the meantime the doctor attended some office and some general business. Gave up the use of morphine in September, 1881, and resumed its use again in March, 1882.

In November, 1880, the Doctor went to Montreal and consulted Prof. Fenwick, who advised resection of the stump of the first amputation. The operation was not performed. In July, 1881, the Doctor consulted Prof. Fenwick the second time, while the stump of the second auputation was healing, after a temporary ulceration. An operation was not advisable at that time.

In July, 1882, the Doctor saw Prof. Hamilton, of New York, in regard to this very painful stump. The Professor was inclined to let the stump alone; but was willing to operate at the Doctor's request; yet he did not think an operation would do much good.

On the 11th July, 1882, the Doctor came to my office to consult me about his painful stump. My advice was to submit to one of two operations: (1) To have a thorough resection of the stump, in fact, a reamputation, leaving abundant flaps; or, (2) To cut off the painful scar-tissue, remove the projecting part of the internal condyle, and bring down from the thigh above a flap to cover the place whence the scar was to be removed. The doctor did not desire a reamputation, but preferred the plastic operation, which I performed on the 13th July, 1882, assisted by Drs. Burge, Snively, Brown and Dickinson, in the following manner: The healthy and normal integument still covering the internal condyle was detached from the condyle, by means of a semi-circular incision, far enough to permit the removal by the saw of a piece of bone, one and one half inch in diameter and over one-half inch in thickness, leaving a smooth surface of cancellous bone on a line with the shaft of the femur. There was normal integument enough to cover this surface. The scar and subjacent bone on the posterior aspect of the stump were removed by the knife and saw, the piece being about one and one-half inch in diameter and about one-half inch in thickness, leaving a smooth surface of cancellous bone on a line with the shaft of the femur. This surface was covered by a large flap taken from the posterior aspect of the thigh above. An incision was made upward on the outer and posterior aspect of the thigh, about six inches. Then the incision was carried downward and inward about three and one half inches, leaving a very broad pedicle to a large quadrangular flap. The edge of the flap looking outward was brought down and stitched to the edge of the integument across the posterior edge of the end of the stump, the entire end of the stump having an excellent covering of normal integument. A moderate-sized space was left above, on the posterior aspect of the thigh, where the flap came from, that was uncovered by integument.

The following points in the subsequent history of this case may be noted:—

1. The morphine habit of the patient was such that, on the 17th July, for instance, three grs. of morphine were administered hypodermically.

From this time till the 27th of July the morphine was daily diminished. Pure water was injected hypodermically in place of the solution of morphine, from time to time, and after the 27th of July all morphine was withheld, and the injections of pure water continued. On the 10th of August the patient was informed of the fact that he had not had any morphine for the previous two weeks, and then he concluded that he did not need any more, as he was doing so well without it. I am indebted to Dr. Brown for the faithful carrying out of this part of the treatme

2. A small portion of the transplanted flap sloughed away about the 20th of July, leaving enough tegumentary tissue to cover the posterior surface of the end of the stump, so as to have only a line of scar-tissue across the posterior border of the stump end, where the large and painful scar was before the plastic operation. By continuous and daily application of adhesive straps the tegumentary covering on the stump end was carried somewhat backward and upward, to meet more completely the edge of the transplanted flap. Also the tegumentary edges above were more and more approximated, till they nearly came together.

3. On the 15th of August the Doctor left the hospital and went home. For some days before going he had walked with his crutches about the hospital, and the grounds of the hospital, and had visited some friends in the city. His general condition had improved very much during his stay in the hospital. He had been greatly relieved from pain, and the future looked bright and more hopeful. He had now a stump, or would have when it was all healed, to which an artificial limb could be fitted. Some time after the Doctor reached home he wrote me a thankful letter, informing me of the good progress he was making. And at the present I think I may write that the case has turned out far better than I could possibly expect. And if another case of painful stump presents itself, I will venture to perform another plastic operation.

—The death of M. Davaine, well-known from his discovery of the bacillus of "Charbon," is announced. Many of his most important works won for him prizes from the Acadèmie des Sciences; among the most important are his *Traité des Maladies vermineuses chez l'Homme et les Animaux;* a *Memoire sur la Contagion du Charbon chez les Animaux;* and *Travaux sur la Septicémie.*

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINICAL LECTURE BY WILLIAM PEPPER, M.D., LL.D.,

Professor of Clinical Medicine.

Reported by Wm. H. Morrison, M.D.

Cancer of the Stomach.

Gentlemen:—I had until recently under my care a lady of about middle age, suffering from tinnitus in the left ear, evidently depending upon some subacute inflammatory change in the middle ear. At times, it seemed to threaten development into Menière's disease, *i. e.*, attacks of vertigo associated with tinnitus, but I cannot say that it ever fully assumed this character. She appeared to be benefited by a course of treatment which consisted in careful attention to hygiene and diet, the prolonged use of quinia with iodide of potassium and counter irritation over the mastoid process and the nape of the neck.

Last spring, while feeling unusually well, she began to complain of a great deal of gastric distress. This was most marked after eating. It appeared to be relieved by a prescription containing pepsin, and the omission of all other remedies, but it soon returned. There was never any vomiting. Examination of the abdomen showed tenderness, but no thickening or hardening could be detected. She came of a healthy family, her mother living to the age of 82, and as far as could be discovered, no member of the family had suffered from malignant disease. There had been no sufficient cause to explain the development of gastric pain; and I therefore, for a time, hoped that it might prove to be a case of gastralgia, which her anæmic condition rendered not improbable. I had, however, observed that it differed from a gastralgia in two particulars. In the first place, the taking of food, instead of affording relief, increased the distress. In simple neuralgia of the stomach, we generally find that the ingestion of food relieves the pain, which again appears as the stomach becomes empty. In the second place, the pain was constant, instead of being paroxysmal, as is usual in gastralgia. I therefore suspected the existence of a gastric ulcer. There was, however, no vomiting, the amount of tenderness was not extreme and the occurrence of simple gastric ulcer in a woman whose surroundings were favorable, who had good food, and who was free from all care, is unusual.

I refer to this case particularly, because we, as physicians are so much in danger of overlooking those grave diseases which develop in our patients immediately under our eyes. We may be attending a patient for some condition, and he begins to complain of this or that symptom. It is either treated lightly or referred to the existing disease. In this way grave diseases sometimes develop, while the physician in attendance does not recognize them, or attributes the symptoms to some preëxisting condition.

As the spring went on, finding my attempts to relieve this pain were unsuccessful, I put the pa-

tient to bed and gave her an exclusive diet of milk, in small quantities at short intervals. I also gave her alteratives, such as bismuth, nitrate of silver, minute doses of carbolic acid, with soda, valerianate of zinc and various other preparations, hoping to relieve the gastric distress; but nothing afforded relief, and she became thinner and thinner. About the middle of June I went away, leaving her under the care of Dr. James Tyson and Dr. Judson Daland. When I returned I found that she had died, and that an autopsy had been held, and that the specimen now before you had been removed.

I propose to examine this with you to-day. The case, as you will have inferred, proved to be one of malignant disease of the stomach. On examining the stomach, I find a number of ovoid masses. I wet one of these and it presents the appearance of a round-cell sarcoma, but a naked eye examination is not sufficient to decide this point. It is, however, some form of neoplasm. I may as well say here that you will often be struck, no doubt, with the laxity with which I use the terms sarcoma and carcinoma in my clinical lectures. The truth is, that the differences between these growths and their minute sub-divisions, as they affect internal organs, is a matter of far greater consequence to you as microscopists and pathologists, than it is to you as physicians. You have a patient in whom the symptoms and the progress of the case show conclusively that some neoplasm has developed in the stomach. That growth is going to kill the patient. The question whether it is an epithelioma, a cylindroma, a carcinoma, or a sarcoma, while of interest in the subsequent microscopical examination, does not alter the prognosis or influence the treatment. I do not use these terms in this manner because I disregard the importance of the study of these minute distinctions between the different forms of tumors; for these distinctions are of extreme importance when we come to consider tumors involving the superficial parts, where they are open to digital examination and operative interference. There we have a different history as regards recurrence after operation, as regards the tendency to extend to adjacent parts, and as regards the formation of secondary multiple growths. A consideration of the minute anatomy is of great importance in external tumors, but in the case of neoplasms affecting internal organs, as the liver and stomach, the same importance does not attach to these minute differences, nor are we able to make them.

As I have said, there is hypertrophy of the glands lying in the curvature of the stomach. This enlargement of the glands extends downward, involving the glands around the aorta and along the spinal column. On section they all present the same general characteristics. They are grayish yellow, sometimes of a pinkish tinge, fleshy, without much juice on scraping, and evidently the seat of some neoplasm.

The stomach itself has undergone remarkable changes. It is exceedingly small, and looks like a contracted, old, diseased, urinary bladder. If filled to its utmost capacity, it would not contain four fluid ounces. The inner surface is discolored and presents a worm-eaten, trabeculated appearance. The walls are thick and rigid. On section they are found to be extensively diseased and the seat of malignant infiltration. There is fusion of the coats of the organ, particularly of the peritoneal, sub-peritoneal and muscular tunics, the mucous coat being less affected than the others. The external and middle tunics are fused into a hard, gristly mass, not less than one-third of an inch in thickness. There is not as much hypertrophy of the muscular layer as we often find, especially in cases where there has been pyloric obstruction. In the present instance the pyloric orifice is not at all obstructed. It is sufficiently large to admit the thumb. As I have said, the mucous membrane is much less involved than the external coats. There is no ulceration of the stomach, and no fungous mass projecting into the organ. This is a remarkable case, and the appearances presented are very unusual.

You see how they account for the symptoms described. There was no pyloric obstruction, and there was, therefore, no vomiting. Vomiting, in cancer of the stomach, occurs most commonly as the result of the attempt of the organ to propel its contents through an obstructed pylorus. This is the reason why the vomiting presents the peculiarities of coming on a certain interval after the ingestion of food, of occurring when the food has reached a certain stage of digestion, and of being followed by complete relief. In other cases of gastric cancer, there is an ulcerated, irritable surface, and the contact of the food against this surface excites vomiting. In such case, the vomiting resembles that which ordinarily occurs in simple gastric ulcer. There was here neither pyloric obstruction nor ulceration of the mucous membrane.

Again, I never was able to feel any lumps or hardening in the epigastrium, on the most careful palpation. The stomach was so contracted that it must have been far back and above the margin of the ribs. Towards the very close of the case, Dr. Tyson thought that he could detect a tumor. This is often the case. While during the earlier periods, and on towards the close, no tumor can be felt, yet, when the patient emaciates to the last degree, and you are able to press your fingers against the spinal column, you may then find a tumor; but in some cases where the glands were not much enlarged, I have felt until the day of death, and have been unable to discover any tumor in the epigastrium.

When you come to study closely the diagnosis between cancer of the stomach, simple ulcer of the stomach, and chronic catarrhal inflammation of the stomach, you will find that there may be in all of these pain, progressive wasting and anæmia, and you turn to the question whether there is vomiting of such character as to indicate mechanical obstruction or ulceration, and whether a careful examination reveals hardening, thickening or a definite tumor, in order to establish the diagnosis. If in the present instance you had depended on these points, the diagnosis would have been simple ulcer, or chronic catarrh. You can easily see, from this specimen, that in a certain proportion of cases you will have to base the diagnosis upon the age of the patient and the steadily progressive, down-

ward course, despite hygiene, dietetic regimen and judicious therapeutics. You do those things which, if it were a case of simple ulcer or of chronic catarrh, would be beneficial, yet you obtain no improvement, or, at the most, but a slight effect. The therapeutic test in connection with the steady march of the case and the age of the patient, will in some cases constitute the sole basis of the diagnosis between malignant disease and simple ulcer and chronic catarrh.

I shall have these tumors examined by the microscope and report the result.

Calculous Pyelitis.

Our next patient is this man, 50 years of age, a native of Massachusetts, but who has been pursuing his occupation of shoe-cutter in this city. His habits have been fairly good. He has used malt liquors moderately. Five and a half years ago he contracted syphilis. This was followed by secondary symptoms. There is no history of hereditary disease on the father's side, but on the mother's side we have a rheumatic history. Ten years ago appear to have occurred the first symptoms which bear upon the present condition; at that time he had dull, burning pain in the lumbar region, burning on micturition and a deposit of brick-dust sediment in the urine. There is no history of any unusual exposure. The attack lasted six months, when he seemed to get perfectly well, and from that time until two years ago he had but little trouble; at that time the same condition returned. I do not find anything in the history of his manner of living, habits of drinking, or of any previous attack of disease, bearing upon this subject, with the single exception that on the mother's side we find the history of a well-marked rheumatic diathesis. His mother died of dysentery, but had passed blood with the urine and had suffered from occasional attacks of gravel. This is the only thing in the history bearing upon these attacks of gravel, with the discharge of uric acid and urates, from which he has suffered.

In addition to the pain, he has noticed the discharge of blood with the urine, in the form of little clots. The pain was usually dull; it never ran into the testicle; it was always worse on the left side and was occasionally accompanied by a sharp pain in the left renal region. During the past year he has been obliged to get up from two to four times during the night to urinate, the passage of urine being accompanied by scalding pain, which was at times very severe. For the past two months there has been a good deal of headache, with beating and throbbing over the back of the head.

Although the appetite has remained good, yet during the last two years he has lost twenty-five pounds in weight. There has been no vomiting. The heart and lungs are normal.

The urine is turbid and there is at the bottom a heavy, smoky deposit. A more recent specimen does not look so bad. Under the microscope the first specimen shows a great deal of blood, a moderate amount of pus, not much mucus, and a few crystalline elements. Some of the pus is old and granulated, and with it there are a few large masses, composed entirely of granular matter, looking like the compound granule cell which is found in old inflammatory exudations. They may be these cells, or they may be large, spherical masses, of granules of urates. It will require a careful chemical examination to decide this. The blood is not much altered in character. He has never passed little pieces of stone.

The most probable condition which would explain such a history is that of a gouty diathesis, with the formation in the kidney, from time to time, of deposits of uric acid and urates, and the formation, more recently, of a deposit of such large size that it cannot escape through the ureter, but is retained in the pelvis of the left kidney, where it has set up an inflammation of the pelvis, causing calculous pyelitis.

This is the most probable explanation of his symptoms, but as he has lost so much flesh, and has such an anæmic and cachectic appearance, it is necessary to examine him carefully, in order to be sure that there is nothing more serious than the disease of the kidney. I find a moderate amount of tenderness over the kidneys, especially over the left kidney. He has not noticed that sudden jars give rise to pain in the renal region, but they do cause distress in the epigastrium. It is not impossible that this pain is connected with the inflammation of the kidney. A deep-seated epigastric pain is sometimes seen in cases of calculous pyelitis; more commonly, you will find that the pain is distinctly referred to the renal region, and patients complain that riding in a jolting car, or over a rough road, or jarring the foot, excites pain in the region of the kidney.

After a careful examination, I can find no reason to suspect any more serious disease than the inflammation of the pelvis of the kidney. Of that I think there is no doubt.

In reference to the urine in calculous pyelitis, it always contains pus in varying quantities. It is not uncommon to find a layer of pus one-eighth to one-quarter of an inch thick in the bottom of an eight f℥ bottle of urine. This is unlike the pus of cystitis, which is mixed with so much mucus that if the bottle is shaken it floats as an almost solid mass through the urine. In calculous pyelitis, the pus is not associated with any large quantity of mucus, and is easily diffused through the urine, rendering it turbid. Blood is frequently present, in consequence of the laceration of the vessels of the delicate mucous lining of the kidney by the calculus. The amount of blood is usually moderate, but occasionally there is a marked tendency to hemorrhage. It may appear in the form of clots moulded in the ureter, but is usually diffused through the urine. On microscopical examination, you find the blood corpuscles exhibiting evidences of having been acted on by the urine, some being crenated, others large and swollen, with their color removed by the urine. Albumen is always found, but its amount is small. It differs in this respect from the albumen in Bright's disease, where the amount is often considerable. In calculous pyelitis, the amount of albumen bears a definite relation to the amount of pus and blood. Where pus exists you will always find albumen, because the liquid in which the pus corpuscles float contains albumen. The same is true of the blood, the liquor sanguinis containing albumen. Where

there are both pus and blood, there may be considerable albumen.

No tube-casts are found. Occasionally in such cases there will be found transparent cylindrical bodies looking like tube-casts, and I presume that they do sometimes come from the tubules of the kidney. They are casts of mucin and of coagulable fibrinogenous matter. They are rarely present and are not associated with evidences of granular change, and contain no imbedded epithelial cells, as is seen in Bright's disease.

In calculous pyelitis there is no dropsy, unless the patient has become very anæmic. There may then be a little puffiness around the ankles on standing or walking. There are none of the secondary changes which are often associated with organic disease of the kidney, such as affections of the heart, retina and other organs.

Therefore, in a case of this kind, if you can eliminate cystitis, it will be easy to eliminate all the forms of Bright's disease.

The treatment of such a case must of necessity be unsatisfactory. It is impossible to dissolve the stone and thus get rid of it. You can hope only to prevent its increase in size, and that thus it will slowly disintegrate, be broken down, and come away in the form of minute granular debris. This does sometimes occur. The way in which we should be most likely to accomplish such a result would be by keeping the urine free from acidity, by preventing an excess of uric acid and acid urates in the system, by promoting rest, so that there should be as small a degree of inflammation as was possible, thus lessening the formation of lymph and pus which might become attached to the stone, leading to its increase in size.

At the bottom of successful treatment is a proper diet. If there is a decided tendency to an excess of urates, if the diathesis is marked, if the habits have been bad, if there has been indulgence in malt liquors to a considerable extent, a radical change will be required. Under such circumstances, if the patient is not very anæmic, a diet of vegetables and milk will be found of benefit. I think that animal food, and especially red meats, should be avoided as much as possible. The white meats may be occasionally allowed. Malt liquors and, in fact, alcohol in every form, should be entirely avoided. All articles of food which task the liver and disorder its action, as the oils and sugars, should be omitted; for we find that where the function of the liver is inadequately performed, there is a greater tendency to the discharge of urates and uric acid than is the case where the liver is acting freely. The diet must, however, be nutritious, for such patients are suffering from a chronic wasting disease, and are always anæmic. They bear a full diet of a suitable character. A diet consisting of the farinacea, milk, vegetables, broths and a small amount of meat, is the best. It is well to give three meals a day and a quart of buttermilk during the day, between meals. These patients must have absolute rest. It is useless for them to try to earn their living by hard work, for this increases the discharge of urates and causes fresh trouble. They should live in an equable climate. If they cannot change their residence, they must remain within doors in stormy weather. In addition to diet and rest, benefit will be derived from the use of alkaline diuretic waters. Some of these have a reputation as solvents for calculi, but I do not believe that any drug or any water has such an action. I believe that when the stone disappears, it is by a gradual disintegration. Undoubtedly these waters, by rendering the urine alkaline and increasing its quantity, will tend to prevent any deposition on the stone. At the same time, the discharge of this large quantity of urine is soothing to the mucous membrane, and tends to allay inflammation. Such waters as the Vichy, either the imported or the Saratoga Vichy, Bethesda, Wickasan, Pollen, and other waters of this class, are very useful. Many of these contain only a small quantity of mineral ingredients, but such as it is is alkaline, and is dissolved in a water of such purity and of such a pleasant character that patients can take large quantities of it. If the urine is decidedly acid, it requires a water containing a considerable quantity of alkaline salts, as the Vichy. If the urine is nearly neutral, a milder water will answer.

You will derive benefit from the use of alterative substances which, by being eliminated by the kidney have a good effect on the inflamed mucous membrane. If there is much pain and irritation, and a good deal of purulent discharge, uva-ursi, buchu, and drugs of that class will be found of service. You can change from one to another of these drugs, as may be necessary. They may be combined advantageously with alkalies, if you do not employ the alkaline waters. The bicarbonate of soda in combination with fluid extract of buchu constitutes a good alterative and alkaline remedy for these cases.

The amount of pain sometimes requires the use of an antispasmodic. Of these, the best is belladonna, which may be combined with the buchu. I have not found it necessary to use opiates, and, indeed, I should dread their use in such chronic cases as these. I have not had the same benefit from hyoscyamus and conium as from belladonna.

These patients often require a tonic and nutrient treatment, and no drug is more frequently called for than iron. It is difficult to say why a disease of this kind should be attended with such anæmia, yet, as a matter of fact, iron is usually indicated. In cases where the appetite and digestion are poor, the bitter tonics and mineral acids should be employed.

I shall put this man on the diet I have suggested, and let him keep at rest. I shall give him a teaspoonful of the effervescing, granulated, Vichy salt, in a glass of hot water, about two hours after each meal. The prima via will then be alkaline, and the water will be readily absorbed.

He will receive the following pill:—

℞.	Quiniæ vel cinchonidiæ sulph.,	gr.j
	Ferri et potassii tartratis,	gr.ij
	Acidi arseniosi,	gr.$\frac{1}{50}$
	Extracti ignatiæ,	gr.$\frac{1}{4}$
	Extracti belladonnæ,	gr.$\frac{1}{8}$
	Extracti gentianæ,	gr.j. M.

Ft. pil. No. 1.

Sig.—To be taken after each meal.

Lastly, counter irritation is of decided benefit

in these cases. I should advise counter-irritation, either by the application of antimonial ointment, or of dilute Croton oil, or of that which I believe to be the best counter-irritant in all deep-seated lesions, and the most agreeable to the patient, the actual cautery. I shall touch the skin over the kidney with the hot iron, which will keep up a counter-irritant effect for three weeks.

I shall have this man carefully weighed, continue this treatment for three weeks, and then see what effect it has produced.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, October 9th, 1882. The President, Dr. Jas. Tyson, in the chair.

Myxomatous Tumor of the Posterior Cervical Region.

Presented by Dr. Nancrede, for Dr. W. G. MacConnell.

The tumor was removed by Dr. J. H. Brinton, at the Jefferson College Hospital Clinic, some ten days since. The patient was a little boy, aged four years, whose parents had first noticed the growth about two years ago. Latterly it has grown with considerable rapidity. It was of firm consistence, lobulated and movable beneath the skin, giving the impression that it was a fibrous tumor. After removal, in addition to the above mentioned characteristics, it was found surrounded by a capsule, and on section looked somewhat suggestive of myxoma, still it was thought by some to be merely a fatty tumor, containing more fibrous tissue than usual.

Microscopic Examination by Dr. MacConnell.—Upon examining a frozen section stained with iodine, meshes of capillaries are seen, in the walls of which the endothelial cells composing the vessels can be distinctly seen. The aforesaid meshes contain the mucoid structure traversed by large, pale, fusiform cells, the processes of which anastomose with each other. In addition many leucocytes are seen, and interspersing the growth, in every direction numerous yellow elastic fibres are readily distinguished.

When presenting this specimen Dr. Nancrede commented on the rarity of such growths.

Dr. S. W. Gross said he had himself presented several gelatinous polypi of the nose, a number of years ago, which were most characteristic examples of myxomatous tissue. He could also recall a specimen of subcutaneous myxoma of the forearm, as well as the hæmatoid myxoma of the breast referred to by Dr. Nancrede. He was disposed to consider it the rarest of all neoplasms of the breast; indeed, he had never personally met with one, and when preparing his work on tumors of the breast, he had written to numerous surgeons throughout the country, who all replied that they had never met with one affecting the breast.

Dr. Formad remarked that he had exhibited a myxomatous fibroma of the labium some years since, and said that the peculiar milky appearance assumed by the fluid when such growths were thrown into alcohol was a good diagnostic point.

Dr. Shakespeare said that his personal experience as to the rarity coincided with that of Dr. Gross. This specimen is one of the rarest forms, as most of the fibrilla consist of yellow elastic tissue. The rarity of myxomatous tumors seems to him to have much bearing on the views of Cohnheim and others as to the etiology of tumors. The observers insist that all tumors spring from the remains of fœtal tissues not made use of in tissue construction, which remain dormant in their embryonal condition until subjected to some irritation, when they develop into the various neoplasms. Now, tissue practically identical with that found in myxomata pervades the fœtus. How, then, is it that portions of this do not remain, to give rise to myxomata? On the contrary myxomata are among the rarest of the neoplasms.

Specimens from a Man who Died with Brain, Lung, Heart, Liver, Spleen, Kidney and Bladder Lesions.

Presented by Dr. J. T. Eskridge.

The specimens showing the above lesions were removed from the body of a man aged 68 years. The patient had become deaf in the right ear thirty years before, while suffering from some brain disturbance. Attacks of jaundice, with gradually increasing permanent discoloration of the skin, had extended over a period of ten years. Since the early part of the year 1877, he had complained of incontinence of urine, an oppressed feeling over the hepatic region, dropsy in the feet and face, and a gradual loss of flesh and strength. The two years preceding his death he had been unable to work, but was only confined to bed five days. During the latter period his symptoms were, in the order in which they were developed, great prostration, scanty secretion of urine, blindness for twenty-four hours preceding repeated convulsions, loss of speech, and almost total inability to swallow, although consciousness was preserved until coma ushered in the death scene. His temperature (axillary) did not rise above 100.5°. The surface head temperature nearly equaled that of the axilla. No paralysis of the muscles of the face or extremities preceded death. The liver during life did not appear to be enlarged or altered in its outline.

The post-mortem examination revealed in the brain engorgement of the veins, with some effusion, slight pia-mater inflammation in the neighborhood of the fissure of Rolando, apparent degenerative changes in the left island of Reil and anterior portion of the left temporo-sphenoidal lobe; in the pleura and lungs old and numerous pleuritic adhesions, lobular and vesicular emphysema of the lungs, congestion of both lower lobes, and a nodule (probably cancerous) of the left apex; in the heart, fatty degeneration, dilated right ventricle and incompetent mitral valves, from ossific change; in the liver, multiple cancer, without an increase in size or a nodular condition of the organ; in the spleen, marked increase of fibrous tissue and atrophy of the gland to one-half or less its normal size; in the kidneys and ureters, the last stages of pyo-

nephrosis, the glandular tissue being nearly all destroyed; the pelves were as large as a good sized orange, and the ureters dilated so as to admit a man's thumb; in the bladder, great hypertrophy of the mucous membrane and decrease of the capacity of the viscus.

Primary Carcinoma of Pancreas and Liver.

Presented by Dr. E. T. Bruen.

The interesting features pertaining to this case are the age of the patient, 24 years, and the rapidity of the abnormal processes. These rendered the diagnosis of malignant disease doubtful, until the appearance of nodular tumors in the liver. The family history was free from hereditary disease. The commencement of the disease dated from September, 1881; death occurred on the 15th of January, 1882. At first the symptoms related solely to the digestive tract, such as a dull, heavy sensation after eating, with acid eructations and occasional vomiting. Subsequently sharp, cramp-like pains in the abdomen were a prominent symptom. After the lapse of a week there commenced general itching, and two weeks later the skin became yellow. This yellowness and itching never disappeared during the history of the case. At the autopsy the gall-duct was obstructed by the enlarged head of the pancreas, so that extreme dilatation of the gall bladder had ensued. This was probably the cause of the jaundice, and not the liver disease itself. The bowels were regular and the appetite good when first seen. The case then presented evidences of partial obstruction of the gall-duct, with digestive disorder, but without the symptoms characteristic of malignant disease of the stomach or bowels. By the middle of December, 1881, the liver dullness extended from the fourth interspace to three inches below the ribs, in the nipple line, and from the ensiform cartilage the line of dullness extended to within one inch of the umbilicus. The hepatic region was tender on pressure, especially over the epigastrium. The patient complained, about this time, of dull pain over the liver, with griping pain in the abdomen. The pulse was 76 per minute. He had lost four pounds since admission, and looked thin. About this time a small inequality was noticed in the surface of the liver, three inches above and a little to the inner side of the umbilicus. The spleen was enlarged. By January 7th the bosselation of the liver became distinct, and the enlarged gall-bladder, rendered irregular by gall-stones, presented a slowly increasing, elastic, tender tumor, situated to the right of the epigastrium and umbilicus. By January 12th the pulse became rapid, 130 per minute, the patient rapidly failed; death occurred January 15th.

Autopsy.—The pancreas was enlarged to double its size, the growth chiefly occupying its head, and compressing the common bile duct. Microscopic examination showed it to be schirrous carcinoma. The liver was thickly studded with nodules of medullary carcinoma, explaining the ante mortem bosselated feel of the organ. The gall-bladder was distended to twice its normal size, and contained a number of gall stones.

Remarks.—The duodenal end of the organ, as is usual, was the seat of the disease. In a paper on thirty nine cases of primary carcinoma of the pancreas, in St. Bartholomew's Hospital Report for 1881, jaundice is stated to be always present, while in twenty-four cases of secondary carcinoma this symptom was noted in but seven severe cases. This is presumably from the secondary growth occurring in some other portion of the organ than its head. Murchison says that the characteristic symptoms of carcinoma of the pancreas are pain in the pancreatic region, sensible tumors and persistent jaundice. To these Dr. Bruen would add intestinal dyspepsia, which differs in some essential features from the dyspepsia of organic disease of the stomach.

Dr. Musser remarked that he could vouch for there being a distinct tumor of the pancreas, as he was present at the autopsy. The case had been under his observation in the dispensary one month prior to admission to the hospital. On account of the age, he was puzzled as to an exact diagnosis, although confident that the cause of the jaundice was obstruction. He noted, among other symptoms, the intense itching of the skin, a point of importance, Sims says, in the diagnosis of obstructive jaundice from that due to suppression. In five cases of tumor of the pancreas he had lately seen, all were accompanied by jaundice.

Dr. Bruen called attention to the uncertainty of bosselation as a symptom of malignant disease of the liver. He had presented to this Society, only two weeks since, a liver exemplifying this condition in a marked degree, where nothing beyond cirrhosis in the stage of enlargement existed. The occurrence of carcinoma of the liver at so early an age, is unusual, although Dr. Pepper had shown a specimen of the disease to this Society some years ago, occurring in an infant.

Dr. Tyson said that there were two points in this case of great interest to him; firstly, jaundice in carcinoma of the pancreas; while it is a frequent symptom, it is by no means an invariable symptom. Seven years ago he presented to this Society the specimens from a case of primary pancreatic carcinoma, where no jaundice had been present, and six months ago he presented to the Society a specimen of enlargement of the head of the pancreas from a patient who also presented no symptoms of jaundice. Secondly, as to the diagnosis from cancer of the stomach, he had noted in his experience, as was mentioned in the history of Dr. Bruen's case, the absence of gastric symptoms. This negative symptom is of importance since the tumor is often detected in precisely the same spot in both these diseases. The absence of gastric symptoms with intestinal indigestion, irrespective of fatty diarrhœa, he considered the most reliable diagnostic points between carcinoma of the pancreas and stomach.

Spindle-Celled Sarcoma of the Small Intestine.

Presented by Dr. W. A. Edwards.

On September 23d, 1882, I was asked to assist Dr. W. F. Atlee in the removal of an abdominal tumor. The patient, æt. 48 years, whose menstruation had ceased at 31 years, first noticed the swelling in April last; on the day of operation she measured thirty-eight inches around the abdomen. The usual incision was made and the

tumor reached, when its surface was seen to be of a dark purple hue, with a net work of large veins ramifying in every part of its serous covering. A trocar and canula were introduced, but nothing but blood followed the withdrawal of the trocar. The sac was then torn open and its contents, of a soft, brain-like consistence, were emptied out. The growth was now turned out of the abdominal cavity. There was no distinct pedicle, but an attachment to the intestine, of about the size of a half-dollar, was seen. Dr. Atlee says, "when I emptied the sac of its soft contents, I examined carefully, with *extreme care*, the part fastened to the intestine, and my fingers passed into the intestinal tube." A silk cord was tied around the attached portion and the remainder of the growth removed. The omentum was attached to the growth for a space of two inches; this was ligated and cut away, and the abdominal wound was closed, etc.

Death occurred on Sept. 25th, at 4 A.M.

This growth sprang primarily from the submucous tissue of the small intestine, and grew with great rapidity, as the patient was only aware of its presence last April, and by September she measured, as above stated, 38 inches.

Microscopical examination of preparations taken from several portions of the growth clearly show it to be a spindle-celled sarcoma, and a most typical one at that. The small intestine is an unusual site for this neoplasm. As far as I am able to ascertain, there is no recorded instance of its occurrence in this situation. My friend, Dr. Formad, to whom I have shown the growth, concurs with me in this statement. On the day of operation I noted, as well as I could, the absence of all secondary deposits. The surrounding intestines and peritoneum were apparently normal, not even unduly hyperæmic. No post-mortem was permitted.

Chronic Parenchymatous Nephritis, Complicating Phthisis Pulmonalis.

Presented by Dr. Jas. Tyson.

My object in showing these kidneys is to illustrate the morbid anatomy of the renal complications which so frequently attends the later stages of phthisis pulmonalis. It is very well understood that when œdema of the feet and legs present themselves in cases of consumption, the end is not far distant, but the renal complication which is at the bottom of such œdema is often overlooked. It is, of course, not impossible that there should be œdema in the last stages of phthisis, from simple alteration in the composition of the blood, a watery state of it, but in the majority of instances it means that the kidneys have become involved. As to the form of disease affecting the kidneys it is acknowledged that it may be either lardaceous disease or chronic parenchymatous nephritis, but I think the impression prevails, it was at least my own until recently, that the amyloid kidney is the most frequent complication. I believe, however, that the chronic parenchymatous nephritis is more common, and it becomes a matter of interest, if not of importance, to be able to diagnose between these two conditions. It is well known that the microscopic and clinical characters of the urine in these two forms of kidney disease are often identical, so that no assistance is afforded by a study of the urine. The history of the case, of course, leads to neither particular form, but suggests both. One criterion only can I recall to aid us, and that is the presence of enlarged liver. So commonly associated is the enlarged amyloid liver with amyloid kidney, that the absence of it almost necessarily precludes the presence of amyloid kidney. At least, I am sure we would err less frequently if we were to consider all cases of renal disease attending consumption, unattended by enlarged liver, to be parenchymatous nephritis rather than lardaceous disease. It is true we often have enlarged fatty liver in consumption, but the degree of enlargement never reaches that of the amyloid liver, and hereafter I shall be inclined to consider all cases of renal disease complicating consumption to be parenchymatous nephritis, unless they are associated with enlarged liver, when I shall conclude that they are instances of amyloid disease.

Dr. Bruen considered that the passage of large quantities of urine and the history of specific disease or of prolonged suppuration preceding the kidney trouble, would warrant a diagnosis of amyloid renal disease.

Dr. Musser would ask whether the heart was hypertrophied and what was Dr. Tyson's experience regarding hypertrophy of that organ in cases of amyloid disease and of chronic tubal inflammation of the kidneys. If not too late he would like to call attention to the absence of cardiac hypertrophy with an infinite degree of obstruction in the renal circulation, in the case Dr. Eskridge had presented. This is in direct opposition to the view held by some that the hypertrophy of the heart is a sequence of the renal obstruction in chronic interstitial nephritis.

Dr. Tyson replied, that in this particular instance he did not see the heart and could not tell whether it was hypertrophied or not. The same law holds good for amyloid kidney as for chronic nephritis; if the case last long enough, hypertrophy is sure to be found sooner or later.

Ecchymoses of Mucous Membrane of the Stomach.

Presented by Dr. J. M. Barton.

The history of this case was that of chronic lung trouble. The stomach upon being opened presented an irregularly shaped extravasation of blood, about two thirds of an inch in diameter. The mucous membrane covering the effusion was healthy, as it was in the rest of its extent.

Dr. Tyson remarked that these effusions are not uncommon, but he had never seen them except in their pin-point form.

Dr. Roberts asked if there had been violent vomiting recently.

Dr. Barton replied that nothing of this sort had been observed for some months prior to death.

—A writer in the *Live-Stock Journal* says that sunflower oil is greatly used for adulterating salad oil. Its leaves are much used for adulterating tobacco. Its oil is unsurpassed as a lubricant, and soap made from it is unequaled for softening the skin.

EDITORIAL DEPARTMENT.

PERISCOPE.

Colic in Children.

The *Medical Times and Gazette* says: In a clinical lecture delivered by Hofrath Prof. Widerhofer, and reported in the *Allg. Wein. Med. Zeitung*, No. 22, we find the following observations:—

By the term colic we understand an intestinal neurosis originating in irritation of a chemical or mechanical kind, of the sensory nerves of the mucous membrane of the intestinal canal. The causes of this irritation arise either in a changed condition of the mucous membrane or in the nature of the contents of the canal. There may also occur purely nervous colic, wherein neither irritating ingesta nor a pathological state of the canal is present, excitement of the central organs being propagated to the nerves of the canal. In infants who are at the breast it is indigestible milk, and especially when this is too rich in fatty matters, that causes the colic; and when children during the first six months are fed with amylaceous food, before a sufficiency of saliva is secreted, colic is also produced. This occurs, too, when indigestible matters are swallowed, such as sand, small pebbles, etc.; and we have good opportunities of observing the operation of this cause in idiots, who often swallow such objects in great numbers. And here we have to meet the question, whether during the period of lactation the mental emotions of the nurse may not induce colic in the infant. It is beyond doubt that frequent mental emotions may induce colic with convulsions, which may be explained by the changes that are induced in the secretion of the milk. In the group of colics induced by irritation caused by the contents of the canal, must be included that caused by constipation, by worms, and by the presence of foreign bodies. Of the morbid conditions of the mucous membrane which give rise to colic, enteritis follicu losa may be especially mentioned, and then scrofulous and catarrhal ulcers, the worst forms being observed in intussusception. Pure nervous colic appears in diseases of the spinal cord, and it may appear in hysterical form, which is not so very rare, and also as intermittent colic, with as regular rhythm as in intermittent fever. We may also include metallic colic, which certainly occurs far more frequently in children than it is diagnosed, as might be expected from the frequency with which toys are made of or contain lead. As regards diagnosis, the purely windy colic produced by the collection of gases which distend the canal and irritate the sensory nerves, comes on with attacks of pain and with distention of the abdomen, ending with the expulsion of flatus. These attacks are paroxysmal, and are frequently accompanied by clonic convulsions, which may last for some minutes, and even for an hour or more. After the cessation of the paroxysm the child is either itself again, or may remain dull and feeble. In the intervals of the attacks there are no essential cerebral symptoms perceptible. The prognosis depends upon the nature of the cause, but it has been questioned whether a colic of itself alone may not prove fatal. Through the long duration of the accompanying convulsions, through the shock and the exhaustion of the nervous system, death may follow, and at the post-mortem no anatomical cause of the fatal termination can be shown. Hysterical attacks of colic especially concern very excitable children, usually nervous girls, and are characterized by violent pains, a drawn-in abdomen, slight convulsions, and obstinate constipation. In the treatment of colic we must first endeavor to remove the cause. In suckling infants, colic is especially apt to occur when the nurse's milk exhibits a large proportion of fat, and in such a case the nurse should be changed. In flatulent colic, oleum chamomillæ or fœniculi may be given, with a drop of tincture of opium, as an oleo-saccharate. In metallic and in hysterical colic, belladonna is the best means; and intermittent colic should be treated by quinine.

Cardiac Affections in Connection with Neuralgia of the Left Arm.

The recent session of the French Association for the Advancement of Science terminated with a communication on this subject, by M. Potain, the following abstract of which is from the *Med. Press and Circular*:—

It is well known that irritation of the digestive organs can produce, by reflex action, dilatation of the right side of the heart, or even of the left ventricle, and, in consequence, peripheric neuralgia. This will be shown in the following cases: 1. A soldier was wounded in the left arm and the limb was amputated. The healing of the stump caused a tension of the nerves, and the young man, long after his recovery, became subject to palpitations, suffocations and hypertrophy of the heart. Injuries of this nature are often followed by hypochondria. 2. Another young man had his forearm crushed, and this resulted in a comminuted fracture, with painful cicatrices. After great fatigue he became subject to palpitations and oppression, so that it was necessary to give up all violent exertion. He had all the symptoms of hypertrophy of the heart, and was also hypochondriacal. 3. A soldier had the left armpit pierced by a ball, and it produced a reaction when healing which prevented his extending his arm and necessitated forced movements, which caused great pain. The patient suffered from palpitations and oppression, and some time after M. Potain discovered that there was a considerable hypertrophy of the heart. Here are three cases of patients who, although with a perfectly healthy heart before the wound was received, suffered afterwards from palpitations and hypertrophy. Here digitalis was indicated. These symptoms differ from those in which the hypertrophy, being situated on the right side, is caused by irritation of the digestive organs. In such cases digitalis is of no use, but one must have recourse

to treatment appropriate to digestion. M. Verneuil also observed an analogous case. A patient from whom the left arm was amputated suffered great pain from the ends of the nerves of the brachial plexus fastened around the bone becoming compressed between the two during the healing of the stump. The patient suffered from hypochondria and cardiac affection. The resection of the arm was followed by cessation of the pain and the cardiac affection. M. Verneuil asked whether the left brachial plexus had not in every case a particular action on the heart, and consequently, if in certain derivative indications on this organ, it would not be better to act on the left arm than in other places? M. Duplouy has also seen a case of the same nature in which they had recourse to the extirpation of a neuroma, with success. M. Ollier also saw a case in which the pain, being in the leg, necessitated the resection of the internal saphena. This fact seemed to extend to the leg the remarks of M. Potain, with reference to the arm. The cases collected up to the present seem to demonstrate that the influence on the part of neuralgia of the left side is considerable; but one need not be surprised to discover that peripheric nervous injuries of the right side exhibit analogous phenomena. M. Leudet knew of an old woman who suffered from peripheric pains in right arm, and who, from time to time, and even when the symptoms were painful, suffered from palpitation, paleness and suffocation. This tends to prove that traumatic neuralgia does not alone take part in the etiology of these secondary cardiac affections, and that spontaneous neuralgia is also capable of acting in the same manner.

A New Material for Casts and Models.

In the *British Medical Journal* Dr. Anthony Bowlby thus describes his process. The articles used are Swinburne's prepared gelatine, 8 oz.; French chalk 14 oz.; honey, 26 fl. oz.; glycerine, 6 fl. oz.; that is, the proportion of 1 part gelatine, 1¾ French chalk, 3¼ honey, ¾ glycerine. Prepare a coloring solution: rub down half a drachm of carmine in half an ounce of water; to this add two and a half ounces of glycerine, and keep in a stoppered bottle; shake the mixture before use.

The French chalk should be perfectly white, and the honey of as light a color as possible ("Furber's Strained Californian Honey" and "Narbonne Honey" are the best). The cost of these materials will be about 7s.

The implements required are two large china pudding dishes, and two saucepans large enough to contain the same. Put all the gelatine into one of the dishes, and add plenty of cold water. Leave it to soak exactly half an hour. While the gelatine is soaking, weigh out the French chalk into the other dish, and add the glycerine. Stand the pots containing the honey in some hot water till it is fluid enough to pour; then add it to the mixture of chalk and glycerine. Mix all well together, and place the dish containing the mixture in a saucepan of boiling water; let it get nearly to boiling heat, and keep on stirring it gently.

To this mixture must now be added the coloring solution, sixty minims of which will make a good flesh color. When the gelatine has finished soaking, turn it out into a clean cloth, and wring out every drop of superfluous water; put it back in the dish, and place the latter in a saucepan of boiling water, over a fire or gas jet.

As soon as the gelatine begins to dissolve round the edges of the dish, pour over it all the hot mixture of French chalk, etc., and keep on stirring for fifteen or twenty minutes, over the fire, till the whole is thoroughly homogeneous; then remove the dish, allow the liquid to cool to about the consistency of treacle, and pour it into the mould. It is better not to use the freshly prepared material for casts, but to pour it out into flat dishes, and, after it has set, keep it for a week or two before using, when it may be readily melted by putting the dish containing it into a pan of boiling water. Should the material have been kept very long, it may be necessary to add a very little water, to faciliate the melting. Considering that it takes some time to set at the temperature of the body, it is not advisable to use the material for taking the mould, for plaster of Paris is in every way better. Moulds made of the latter material should be well dried and oiled, after which they should be painted with spirit varnish, and again oiled, before use. The cost of the material is slight, and the time occupied in making a considerable quantity is about one hour, or rather more.

Casts thus prepared present a very great resemblance to human flesh, both in color, texture, and translucency. They are very easily painted, and form an admirable ground work for the depiction of skin diseases. As to their durability, I cannot speak with certainty, having none which have been made more than ten months. It is very necessary to keep them in a dry place.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——One of the most annoying of children's diseases is incontinence of fæces. A successful method of treatment of it is described by Dr. Geo. B. Fowler, of New York City, in a late reprint. The method is by suppositories of ergot. This is a hint well worth remembering.

——Prof. Chassaignac used to use his écraseur for fistula in ano, and in a late reprint the practice is advocated by Dr. J. M. F. Gaston. Although most surgeons dissent from his views, he gives various good reasons why, in many cases, it is the best practice to have recourse to this instrument.

——Walsh's "Call Book and Tablet" is a conveniently arranged visiting list for physicians, the present edition, for 1883, having been carefully corrected and improved in various particulars. It is durably bound in Russia leather, and of commodious size. Published by Dr. Ralph Walsh, Washington, D. C.

——Probably none of our chemists have given equal attention to the analysis of water as Mr. Reuben Haines, of Germantown, this city. His essays on that subject deserve the careful study of sanitarians, hygienists and chemists. His latest is entitled "Notes on Water Analysis," and in the form of a neat reprint can be had of the author.

——The Progress Pub. Co., of Cincinnati has begun the publication of a serial work, entitled, "Pathological Anatomy, Pathology and Physical Diagnosis." By J. A. Jeançon, M.D. It is in large 4to form, and is to have one hundred full-page illustrations and 100 pp. text. It will be sold to subscribers at $1.00 per part, and will be complete in 25 parts. Part I, which has been sent us, promises extremely well, both in text and illustrations, the latter being accurately drawn and excellently colored.

——Dr. John V. Shoemaker, of this city, has been making some fruitful studies in therapeutics, for which he merits the thanks of the profession In three reprints before us he treats respectively of the therapeutic action of potassium chlorate, the treatment of syphilis with subcutaneous sublimate injections, and the oleates and oleo-palmitates in skin diseases. The last mentioned is particularly interesting, and we can speak from experience of the value of several of the recommendations it contains. These reprints can be had of the author, 1031 Walnut St., Phila.

BOOK NOTICES.

The Diseases of the Liver, With and Without Jaundice, with the Special Application of Physiological Chemistry to their Diagnosis and Treatment. By George Harley, M.D., F.R.S., etc. Phila.: P. Blakiston, Son & Co. 1883. 8vo, pp. 751, cloth. Price $5.00.

Dr. Harley has long stood among the leaders of the profession in London, and for many years has studied hepatic diseases with peculiar attention. Twenty years ago he brought out a treatise on jaundice, which was highly appreciated, and in the present volume sums up the results of his wide observations on all the affections of the organ involved in this disease.

His especial point, as indicated in the title, is to bring prominently forward the relations of physiology to the forms of disease. Too exclusive attention, he thinks, has been paid to pathology. It has been regarded as a science apart. The great truth has been overlooked that the same fundamental laws regulate the phenomena both of health and disease.

With this as his guiding principle, he approaches the complicated problem of "liver complaints" and "biliousness" with a much stronger hand than his predecessors in that field. Afflicted as many districts of our country are, with many and puzzling forms of these maladies, we believe Dr. Harley's volume will be a welcome addition to many a library.

He starts out with a clearly worded chapter on the chemistry, physics and physiology of the liver, discusses the etiology of jaundice, describes in general terms the signs and symptoms, the treatment and remedies of hepatic disease, and then passes on to take up, one by one, the particular maladies of the organ. A special chapter is devoted to the gall bladder.

The last chapter is entitled "general hints to aid in the diagnosis and prognosis of diseases of the liver," and is, we venture to say, the most useful of any writings on this subject, of equal extent, in our language.

Two chromo-lithographs and thirty-six wood cuts illustrate the work.

The publishers announce that this edition is published by special arrangement with Dr. Harley, and is the only authorized American edition. Readers may make a note of this.

Sanitary Houses and How to Select One. By F. A. Bond, M.B. Edin. Univ. London: Kegan, Paul, French & Co. 1882. pp. 60. Price one shilling.

The great want of interest displayed by the average American citizen in matters pertaining to the science of hygiene is truly disheartening. It is not so much their fault as their misfortune, since they have not been taught to appreciate its beneficent value. That they must be so instructed is a foregone conclusion, since hygiene is the most progressive of all sciences. This little work before us we can commend as a safe guide to put into the hands of the average man or woman looking for a home. It is short, concise, and contains much excellent advice.

How To Make the Best of Life. By J. Mortimer Granville, M.D. Boston: S. E. Cassino, 1882. fol. 96. Price 50 cents.

Dr. Granville has written several small popular works on the preservation of health, and if they are all as meritorious as the little one before us, we can recommend them as worth the price asked. The subjects treated of in this book are, "Health," "Feelings," "Breathing," "Drinking," "Eating," "Over-work," "Change," etc. While, from the size of the book, all these subjects are necessarily but cursorily discussed, yet the average intelligent man will find some very useful hints to aid him in the warding off of disease.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D.,
JOSEPH F. EDWARDS, M.D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE HIGHER EDUCATION OF WOMEN.

There is a professional, as well as a popular, aspect of this question, which is at present agitating our community; there is a physical, as well as a moral, question to be considered in deciding this problem. In a general way, it must be said that women have just as much right to receive a scientific education as have men; we are all human beings, made upon the same fundamental plan, and it would seem unjust to deny to any one sex, as a sex, that education which is the lever that lifts the human animal above the brute creation.

But, will it be really to the ultimate benefit of women to receive this higher education? To those who are physically and mentally capable of receiving it, we must answer in the affirmative. That there are so few women to be found in the sphere of public intellectual life, does not, we think, argue their natural unfitness for such positions, but is rather the direct result of the denial of opportunities to acquire the necessary qualifications to properly fill such positions.

No matter what opportunities may be offered to women, the proportion which they will hold to men in the scientific world will ever be very small.

We trust that we will be pardoned (for we mean no disrespect whatever) when we say that it is not the *true womanly* woman, but rather the *masculine* woman, who hankers after this higher education. We are speaking in all sincerity, from a scientific standpoint, and mean no disrespect to any one.

We clearly recognize two distinct types of womanhood, between which all degrees of each are to be found.

On the one hand, the timid, confiding, trusting woman, who, after completing her school or convent education, soon comes to realize that her mission in this world is a *domestic* one, with all the mingled trials and pleasures which that word implies.

On the other hand, we see the self-confident, self asserting, self-reliant, fearless, masculine woman, who feels irresistibly impelled to push forward into the realms of science, and for whom the domestic duties have but a secondary attraction.

These two types are both admirable; the one lovable, the other grand and noble.

The first never gives a thought to the "higher education of women;" the second desires and demands it.

Let her have it. If she be capable, she will make her mark; if she be not, Darwin's beautiful law will come into play, and she will disappear.

In a word, the number of women who demand scientific education are comparatively few; they possess many masculine characteristics, and are entitled to masculine privileges. If you give them the chance they may, perhaps, fulfill their earthly mission; if you deny them, you do them an injustice, by refusing a request the granting of which could do them no harm. Therefore again we say, grant their request.

CHOLERA.

Fore-warned is fore-armed. It may not come, but no one can say so, absolutely, and it is always well to be prepared for danger.

Cholera is now very prevalent in the Eastern Archipelago. In 1832 and in 1847 this dreaded disease traveled in a westward direction across Afghanistan, Persia, Syria, and the Valley of the Danube. Fears are now entertained in France that the disease may take a shorter course, up the Red Sea and through the Suez Canal into the Mediterranean. If it does, the greater part of Europe will be in danger, and if the disease gains a foothold there, look out for its appearance in our own country.

But what shall we do? the old, old, question often asked, repeatedly answered, and as often disregarded. Does it not seem strange?

In a word, we have it in our power to absolutely prevent the introduction of this plague into our country, even though it should devastate all Europe.

This preventive power lies in two words which are the foundation stones of all sanitary science, viz.: *disinfection, isolation.* Disinfection means cleanliness, for a *clean* place can contain no germs of disease. Isolation really means thorough and efficient quarantine. Stir up the scavengers in your neighborhood; they are a remarkably lazy set, and soon fall into inactivity, unless continually spurred on to work. The country must be cleaned (we mean the filthy cities of this country), and our authorities must be on the watch, alert, to catch the first reports of the disease in Europe and to immediately institute the strictest quarantine, isolation and disinfection. We trust the disease will not attempt to visit us, but if it does, let us be prepared to give it the cold shoulder.

TRAINING SCHOOLS FOR NURSES.

The Washington Training School for Nurses held its fifth annual meeting, in Washington City, a short time since. Dr. J. M. Toner presided. In his address he vividly described the high duties of professional nurses, and paid a glowing tribute to Florence Nightingale. There are now eighteen training schools for nurses in the United States, the two oldest of which exist in Philadelphia, viz.: The Philadelphia Lying-in Charity and Nurse School, founded in 1836, and the Nurse's Training School of the Woman's Hospital, founded in 1863

The importance of professional nurses cannot be overrated and, we fear, is but very imperfectly appreciated.

The average physician comes into contact with them only when he meets a monthly nurse in a case of midwifery, when, partly through early prejudice, and partly on account of the fact that the majority of these women are absolutely destitute of all that goes to make a good nurse, he conceives a violent dislike to the whole class.

While this feeling is natural, it is unfortunate, because, were things as they should be, it would be unnecessary.

Some of these monthly nurses are really very good, worthy and efficient persons, and it is to make *all* such, that training schools are designed.

Every physician realizes and admits the great advantages to be derived from capable nursing; indeed, we look upon it as the greatest accessory to our art, even, in many cases, as an indispensable necessity for the successful termination of sickness.

But where to procure this trained assistance, is the problem that has long bothered many physicians.

To supply this want, training schools exist, and that they may be successful in their missions, they must receive the hearty and active coöperation and support of the profession.

Notes and Comments.

An Easy Method to Discover the Tubercle Bacilli in Sputa.

Prof. Baumgarten has just published in the *Ctbl. f. d. Med. Wiss.*, 25, 1882, the following easy method to detect in the expectorated matter of phthisical persons the pathogenic tubercle bacilli.

Phthisical sputa are dried and made moist with very much diluted potash lye (1 to 2 drops

of a 33 per cent. potash lye in a watch glass of distilled water). The tubercle bacilli are then easily recognized with a magnifying power of 400 to 500. By light pressure upon the cover-glass the bacilli are easily pressed out of the masses of detritus and secretion. To prevent, however, the possibility of mistaking the tubercle bacilli for other septic bacteria, or vice versa, the following procedure is necessary: after the examination just mentioned, the cover glass is lifted up and the little fluid sticking to its under side allowed to dry, which is done within one or two minutes. Now the cover-glass is drawn two or three times rapidly through a gas flame; one drop of a diluted (but not too light) common watery anilin solution (splendid for this purpose is the watery extract of a common anilin ink-paper) is placed upon the glass. When now brought under the microscope all the septic bacteria appear colored intensely blue, while the tubercle bacilli are absolutely colorless, and can be seen as clearly as in the pure potash lye. We may add, however, that Klebs considers his own method preferable.

As the whole procedure does not take longer than ten minutes, it is to be recommended in general practice. The consequences of Koch's important discovery become daily more apparent, and their application more practicable.

Sloughing of Bowel—Spontaneous Recovery.

Dr. T. Sumter Means reported a case that well illustrates the reparative power of nature, at the last meeting of the South Carolina Med. Ass. (*Transactions*). The patient was crushed between cars, receiving a contusion of the abdomen, which, when seen (eleven days later), was much distended and discolored. About the junction of the ilium and cæcum there was a small opening in the abdominal wall, through which the nurse thought she had noticed an escape of bubbles of gas. On removing the plug from this opening there was a discharge of about a teacupful of fecal matter. His bowels had been freely moved several times by a mercurial cathartic. Carbolic acid dressing, with light poultices and McMunn's elixir, to control peristalsis, constituted the treatment. The knees were kept drawn up, to relax abdominal muscles, beef essence and milk punch, but no solid food was allowed. For a few days the rent grew larger, until it was one inch in diameter, and the fecal matter continued to be discharged for twelve days, when a scab formed that closed it. After about three weeks his bowels were opened by enema, and he continued to improve until, in three months from receipt of injury, he was completely recovered.

Brain Syphilis.

Dr. Brandies presented recently to the New York Society of German Physicians (New York *Med. Jour.*), a young man who had contracted a chancre six years previously. He presented undoubted evidences of having had secondary syphilis. About six months since he had an epileptic seizure, and subsequently two more such attacks. The patient complains of deafness and vertigo. On examination both ears were found affected with otitis media. In walking, a lack of co-ordination of movements was noticeable. Great improvement has taken place under the use of iodide of potassium. The hearing became much better, and the patient could walk for some distance with closed eyes. Dr. Jacoby believed this to be a case of brain syphilis, and he was inclined to locate the lesion in the rhomboid fossa, near the exit of the acoustic nerve.

The Respirator in Syphilis.

Dr. W. S. Oliver thus writes in the *Lancet*:—

The treatment of syphilitic ulcers of the tongue, mouth, and fauces by respiration of iodine and carbolic acid, etc., has proved so successful in numerous instances which have come under my notice of late, that I am desirous of giving it publicity in your columns. For the past two years this form of syphilis has been peculiarly prevalent in this command, and, as usual, proved so tedious of cure, and so liable to recur under the ordinary treatment, constitutional and local, generally adopted, that I decided this year to test the efficacy of the "respirator," and I was gratified to find that the results, in all instances, were most satisfactory. The period of trial is as yet too brief to furnish reliable evidence of the constitutional and permanent effects of this treatment; but certain it is that locally its action is most prompt and palpable, all ulcers assuming a healthy appearance generally in forty-eight hours, and wholly disappearing in ten or twelve days. Immediate relief is also afforded from any panic or discomfort previously caused by the disease. After free purgation the only treatment needed is the use of the "respirator" for four hours daily, two morning and evening, after breakfast and tea. The solution I generally use is Coghill's combination of iodine, carbolic acid, and creasote, and I prefer oakum as the mate

rial for its retention. The form of "respirator" I have adopted is one I have devised myself, and is furnished with a detachable perforated diaphragm, which admits of its being thoroughly cleansed and purified for use in different cases.

Pathology of Sympathetic Inflammation.

By the anatomical examination of a series of eyes, when the morbid condition of one caused a sympathetic affection of the corresponding organ, Dr. W. C. Ayer's (*Arch. f. Augenhlkd.*, xi, 3) comes to the following conclusions:—There are two ways by which the sympathetic processes may be transferred, one is the optic neuritis, the other the cyclitis, or both act at the same time. Those eyes which induce the sympathetic lesion within the first 15 to 20 days, transfer first the pathological condition to the optic nerve of the eye sympathetically diseased; in the other cases, where the ciliary nerves establish the transfer, the sympathetic affection usually appears later. In nearly all such cases A. was able to demonstrate the transfer of the morbid lesion by the ciliary nerves. In the eye first diseased, always a pathological change of these nerves were found under such circumstances.

The Abortive Treatment of Gonorrhœa.

Dr. Beresford Ryley, writes to the *Lancet* on this subject. He reasons first, that two diseased surfaces in constant and close apposition with each other are unfavorably placed for recovery, therefore he separates the walls of the inflamed urethra by injections of hot water retained for twenty minutes or longer, which he accomplishes by the aid of a simple spring forceps to hold the extremity of the penis. Secondly, the gonorrhœal discharge must perpetuate and increase the inflammatory stage, therefore the injections when frequently used will have a salutary effect in this direction. Thirdly, it being well known that hot fomentations and applications are soothing and emollient in all inflammatory conditions, it follows that these hot injections and hot baths and the application of flannels wrung out of hot water must be beneficial.

And, lastly, certain drugs that have a styptic effect upon the genito-urinary mucous tract are plainly indicated. But experience proves that they can only be administered with benefit after the more acute symptoms have subsided. I therefore give the liq. copaivæ comp. when that stage has been reached, which is generally the case within a few days under the treatment indicated, and at the same time add three drops of liq. plumbi to each ounce of the injection, which must now be made with distilled water, and used less warm, or altogether cold. In some cases weak injections of nitrate of silver or chloride of zinc may now be of great use. I need scarcely add that the regimen, alimentary and medicinal, must be strictly non-inflammatory in the acute stage. Will you permit me to say, in conclusion, that I think the *modus operandi* of Mr. Cheyne's treatment and mine is very much the same—viz., separation of the walls of the urethra, dilution of the discharge, and lubrication of the inflamed surfaces with the cocoa-butter bougies. His objection to injections, that their effects "are only momentary," cannot apply to the manner in which I recommend them.

Subnitrate of Bismuth for Cancrum Oris.

Dr. C. J. McGuire, of New York (*Medical Gazette*), claims specific action for the local application of subnitrate of bismuth for cancrum oris.

Nineteen children were attacked with the disease. Dissatisfied with the results of his treatment in the four first cases, he determined to try the effects of subnitrate of bismuth applied externally to the affected parts. The result was the immediate improvement in the appearance of the ulcers, and eventually a complete cure. From the first appearance of the disease in the institution up to the present time 24 cases were treated, including the 4 that proved fatal; out of 20 cases treated with subnitrate of bismuth only 1 resulted fatally.

Special Reports.

No. X.—Ophthalmology.

BY CHAS. S. TURNBULL, M.D.,

(*Continued from p.* 475.)

Michel Jul. *Affections of the Eye from Disturbed Circulation in the Carotid.* (*Beiträge zur Ophthalmologie. Festgabe zur Feir des 25—jährigen Jubilaums von Horner Weisbaden*, 1881.) If a carotid artery be compressed in a man, a paling of the papilla of the corresponding side, a fainter column of blood in the arterial vessels, and a diminution in width of the venous retinal vessels, may be observed for a short time. The stage passes quickly, and great venous stasis and absence of venous pulsation show themselves. A similar venous stasis of the retina is visible when one arm is stretched upward. Ligation of one carotid is followed, immediately

after the operation, by complete arterial and venous anæmia; later, by filling of the collateral channels; but a venous hyperæmia persists, on account of the diminution of arterial pressure.

The alteration is observed in the eye corresponding to the ligated carotid. In the venous system of the side opposite to the ligated vessel, a stronger rhythmical pulsation can be seen. Atheroma of the carotid is in intimate relation with opacities of the lens; the so-called senile cataract, as well as unilateral cataract with unknown cause, finds in this a satisfactory explanation. (*Arch. f. Ophthal.*, Vol. xi, No. i.)

Noyes. *Cure of Cataract by Electricity.* (*Amer. Ophth. Soc.*, at Newport, 1881, July 27th, 28th.) A seeming cure of cataract by electricity proved to be a case of choroiditis, in which, under electrical treatment, flakes in the vitreous had disappeared. (*loc. cit.*)

Sorokin. *Parasitic Growths in the Eye. Der Arzt.* No. 16. The forms observed by Förster and Gräfe do not belong to lepto hrix. In the cornea of an eye which had perished from panophthalmitis, he observed long, thin, opaque filaments; they are thicker than those of leptothrix buccalis, and show a tendency to twist themselves lengthwise around each other, or to assume a curved form. Attempts at cultivation failed, excepting in human blood; here the filaments lengthened, gathered themselves together in a curved form, showed transverse marks of segmentation, and divided into two to five pieces of different length; the process lasted from twenty-five minutes to one hour. The new pieces congregated, and thus formed additional bundles. This is a new form, *leptothrix oculorum* Sorokini. In an eye effected with panophthalmitis after iridectomy, and also in an existing catarrh of the lachrymal passages, he found filaments dividing dichotomically, having a thickness of 2 or 3 division marks of the micrometer; they also exhibited transverse division, and thus formed widened rings. The twigs branch off only where there are transverse divisions. Besides these, there were folds of cells of various size and shape. All attempts at cultivation failed. (*loc. cit.*)

Wolfe, J. R. *On Artificial Pupil. Medical Times and Gazette*, June 1, 1881, p. 611. In a lecture delivered at Anderson College, W. gives the indications for the operation, and among the contra indications, says that in occclusion from specific iritis no operation should be attempted till twelve months after all disappearance of irritation in the eye.

During the twelve months' interval the patient must be kept on iodide of potassium and mercury. He described the operation and points of selection. He deprecates the employment of iridotomy. (*loc. cit. Fitzgerald.*)

Theobald. Remarks upon the use of *Duboisia in Ophthalmic Practice*, with report of a case in which *alarming constitutional symptoms* followed its application to the eyes. *Maryland Med. Jour.*, vol. viii. T. thinks the toxic action of the drug more likely to manifest itself in an uninflamed eye than in one that is inflamed. Its unpleasant effects are manifest within an hour after it is applied to the eye. (*loc cit. Swan M. Burnett.*)

Haab. *Anatomical Examination of an Anophthalmus, at the age of* 27. Ophthalmological contributions on the occasion of the Jubilee of Horner. Weisbaden, 1881. The ocular muscles normally developed; the globes appeared as small nodules the size of a bird-shot; the optic nerves were delicate, thin threads, the orbits of normal size. Sclerotic, choroid, pigment epithelium, retinal elements, and vitreous could be demonstrated in the eye, but no conjunctiva, cornea, iris, ciliary body and lens. The optic nerve consisted only of connective tissue. The optic tracts could be followed as white strings up to the corpus geniculatum internum. The corpus geniculatum externum was absent, the pulvinar thalami optici distinctly smaller. The thalamus and corpora quadrigemina could not be distinctly traced. (*loc. cit.*)

Hirchberg. *Coloboma and Microphthalmus. C. f. A.*, September. Congenital microphthalmus is in some cases combined with amaurosis, opacity of the lens, diminished tension, cyclitis and coloboma of the iris. Hirchberg has observed four cases of this kind. (*loc. cit.*)

Leydig. *The Eye-like Organs of Fishes.* Bonn, 1881. Certain spots upon the ventral surface of some sea-fishes, which by Leuckart had been explained as secondary eyes, are not taken as organs of special sense by Leydig, who supposes that they are allied to the spendo-electrical or electrical organs of other fishes. (*loc. cit.*)

Michel. *Iris and Iritis.* G. *Arch. f. Ophth.*, vol. xxvii, 2. I. Histology. The proper substance of the human iris is enclosed between two membranes; the anterior limiting membrane is a delicate layer of endothelial cells; the posterior one consists of peculiar cellular elements; upon its posterior surface is a pigment layer of nearly round, irregularly arranged, pigmented cells. Behind the endothelial membrane is a layer of anastomosing cells, interspersed with

lymphoid cells, and resembling the reticulated structure of the lymphatic glands; for this reason Michel calls it the reticulated layer. Behind this layer, and partly projecting into it, is a radiating trabecular arrangement of connective tissue fibres; these trabecles support the numerous blood vessels and nerves; they are covered with flat cells, and the spaces between the trabecles and between these and the posterior limited membrane, are filled with a reticulum of cells, arranged in a similar manner as in the reticulated layer. For this layer Michel proposes the name "vascular layer." From in front, backward, the iris consists, therefore, of the following layers: 1, anterior limitans (endothelial membrane); 2, reticulated layer; 3, vascular layer; 4, posterior limitans; 5, pigment layer. From its histological elements, the iris would appear to be a modified glandular structure. The system of lucunæ are lymphatic cavities in which the nutritive material, filtered from the blood vessels, is collected; the anterior chamber is a large lymph cavity. II. Development. 1. In the human embryo, the development of the sphincter portion takes place very early; that of the ciliary portion at the end of the sixth month. 2. The pupillary membrane is a pellicle which contains nuclei, epithelial cells and blood vessels; the latter two disappear, and the pupillary membrane becomes the endothelial layer upon the anterior surface of the iris. 3. At a certain period of fœtal life there is a fold in the ciliary portion, the plica iridis. If the two opposite surfaces of the pupillary membrane are not separated, the so-called membrane pupillaris perseverans will be formed. 4. At a certain period of fœtal life the posterior portion of the iris shows three layers: the pars ciliaris retinæ, the pigment layer, the limiting membrane. The pars ciliaris retinæ becomes pigmented and disappears. 5. The pigment layer and limiting membrane send projections into the sphincter portion; the largest and most strongly pigmented projection is at its peripheric portion, the so-called pigment spur. 6. During embryonic life smooth muscular fibres cannot be demonstrated in any part of the posterior limiting membrane. 7. During the last months of embryonic life, and in the new-born, the posterior portions consist of only two layers, the pigment layer and the limiting membrane. 8. The limiting membrane must be taken as a continuation of the primitive limitans retina. 9. The projections from the posterior limiting membrane into the sphincter are the connective tissue septa, which separate the bundles of the muscle. The pigmentation of the so-called stroma of the iris is of post-fœtal development. (*loc cit.*)

Ogneff. *Histiogenesis of the Retina. Centralblatt, f. d. Med. Wissenschr.*, No. 35 1. In the earliest stages (rabbit's embryo) the retina consists throughout of spindle-shaped cells with oval nuclei and a narrow zone of protoplasm. From both ends of the cells, which lie on a different level, both inward and outward, are processes which are vertical to the outer surface of the retina, and which pass through its entire thickness. Here and there upon the outer surface of the retina are large transparent elements with limiting membranes which are not found at this stage. 2. The next changes are that the innermost cells become divided, larger and rounder. Their nucleus becomes more distinct, and they send off several processes which again form multiple ramifications. The processes, which run inward, and of which each cell sends off one only, turn and take a course parallel to the inner surface of the retina. They are the first indication of the layer of nerve fibres. The outermost layer of cells is distinguished by thick, at their inner end, and foot-like projections; these elements are the embryonic Müller's radical fibres. The formation of the nerve cells and of Müller's fibres is therefore one of the first embryonic changes in the retina. 3. Then between the nerve fibres and the spindle-cells above them there appears a small stripe, the first indication of the molecular layer. At this period the layer consists of numerous processes of the nerve cells, of the straight columns of Müller's fibres and of processes of the spindle-cells and numerous very small granules. 4. The layers become more and more developed; especially the molecular and nerve cell layers become more sharply defined and thicker. Free nuclei and roundish cells appear in the molecular layer. The differentiation of the retinal layers becomes completed by the formation of the rods, and of the two layers and granules. The rods are processes of the outermost layer of cells, which grow beyond the outer limiting membrane. The retina of the mammalia shows the same process of development as that of the birds and batrachia. (*loc. cit.*)

Wälchli. *Microscopical Examination of the Colored Globules in the Retina of Birds. G. A. f. Ophth.*, vol. xvii, 2. There are three kinds of coloring matter in the globules, sphærorhodin, sphæroxanthin and sphærochlorin. (*l. c.*)

Wall. *Congenital Absence of the Eyeballs.* N. Y. *Med. Rec.*, March 26, 1881. The appendages of the eyes and the lachrymal glands were present. (*l. c.*)

Wetschtamon. *An Anomalous Structure of the Human Eye. Aerztliche Zeitung*, Nov. 1881, No. 36. Absence of both irides. Both eyes turned in and up. (*l. c.*)

Wiethe. *A Case of Congenital Deformity of the Papilla. Arch. Ophthal.*, vol. xi, No. 1. The papilla showed two dark elliptical depressions. (*H. Magnus, l. c.*)

Deutschmann. *On the Physiological Chemistry of the Fluids of the Eye. Arch. f. Ophth.*, vol. xxvii, 2. In the fresh aqueous humor there is 0.03 of albumen. In the vitreous there is much more than in the aqueous. It increases in both after death, more rapidly in the aqueous. (*l. c.*)

Pflüger. "Internat. Ophth. Congr. in Milan," p. 197. Atropine reduces the intra ocular tension. Eserine increases it, also the continuous current. Experiments to be continued. (*loc. cit.*)

Butz. Preliminary communication on the examination of *Physiological Functions of the Periphery of the Retina. Arch. f. Anat. und Phys.*, Phys. Department, 1881, vol. 5. The sensibility to light of every wave length increases from the centre toward the periphery up to 30°, then decreases more or less rapidly, according to the kind of light. The increase in the sensibility to all kinds of light varies; in the most peripheric part of the retina it is highest for violet and lowest for red.

Goltz. *The Functions of the Cerebrum. Gesam. Abhand.* Bonn, 1881. The supposition of circumscribed centres in the cerebral cortex, with special functions, is untenable, consequently there is no part of the cerebrum which is distinctly set apart for vision. The visual disturbances which occur after traumata to one side of the cerebrum are symptoms of a general dullness in all the senses, and are caused by a general intellectual dullness. Goltz proposes the term cerebral diminution of sight, or cerebral amblyopia. (*l. c.*)

Landolt. *The Functions of the Retina. Arch. d' Ophth.*, vol. 1, 3. The retina has three functions, the perception of light, color and form. That of light is distributed over almost the whole retina equally, only in a small part around the fovea centralis it is somewhat greater. Perimetrically it extends outward 100°, inward 60°. The color perception decreases rapidly toward the periphery, but by higher intensities of light, colors are recognized to the limit of the field of vision. Perception of form decreases rapidly toward the periphery, so that at 50° from the point of fixation they are no longer recognized. The cause is want of practice. (*l. c.*)

Parent. *Optometry, Ophthalmoscopy and the Inverted Image. Rec. d' Ophth.*, 1881, Sept. Refraction can be determined in the inverted image in two ways. (1) By gradually moving the object lens to or from the eye, and noticing the change in the size of the image. In emmetropia it remains the same, whether the lens is held nearer to or further from the eye. In hyperopia the size of the image decreases when the object lens is removed from the eye examined. In myopia it increases under the same conditions. (2) By observing the parallactic displacement in comparison to a certain amount of upward motion of object lens. If we move the lens in the vertical plane, the image changes as follows: in emmetropia to an equal extent, in myopia to a lesser extent, in hyperopia to a greater extent. If we place certain glasses before the eye examined, and make these experiments, we can almost tell the amount of the anomaly of refraction by trying until the motions correspond to what they should be in emmetropia.

Schön. *Venous Pulsation in the Retina. Klin. Monasbl. f. Augenheilk.*, p. 345. 1. Venous pulsation is a phenomenon of impediment. 2. The exit of the usual quantity of venous blood is diminished by depression. 3. The pulsation is brought about by arterial pulsation. 4. The region in which this happens must include the optic nerve up to the lamina-cribrosa. (*l. c.*)

Bjernum. *Hemianopia for Colors. Dansk. Hosp. Tidende*, January 18, 1881. Total color-blindness in the left half of the field. The margin passed precisely through point of fixation, in a vertical direction. There was an acute brain trouble: at least, the patient complained of a severe headache, and died suddenly. He was 39 years old. Unfortunately there was no post-mortem. Bjernum cites this case in upholding a theory of the existence of a color centre. (Samelsohn reported a similar case in November of last year.) (*l. c.*)

Brailey. *Report* of the Committee of the Ophthalmological Society *on Color-blindness*. Trans. Ophth. Soc., vol. 1, p. 191. *British Medical Journal*, April 23, 1881. *C. f. A.*, Sept., p. 289. There were 18,088 patients examined, 16,431 men, and 1657 women—with Holmgren's test. Of the men, 949 were Jews, showing 4.9 per cent., and 491 Quakers, showing 5 9 per cent.; 145 deaf mutes with 13.7 per cent. of color blindness. Of the remaining 14,846 men (of all conditions) there were 3.5 per cent. color blind.

Among the women there were 730 Jewesses

with 3.1 per cent., 122 deaf mutes with 2.4 per cent., and 216 Quakers with 5.5 per cent. Among the remaining 489 women, 0.4 per cent. were color blind. The unusual number among women is explained by the fact that Brailey says that in them it was not very pronounced. It was first doubted in the reference in the *Centralblatt* and absolutely contradicted by Cohn, of Breslau, that such a difference is found between the higher and lower classes, as Brailey says that in the lower class he found 3.7 per cent., and in the higher only 2.5 per cent. All who could not distinguish the paler shades were classed as slightly color blind; those who confounded red and green as pronounced. There were 615 of the latter class, and three cases of total color blindness. It was very seldom that blue and violet were mistaken for one another. Those who compared pink with deep blue, or violet and scarlet with dark green, were considered red-blind. Those who compared pink with gray or green, and scarlet with light green or light brown, were considered green-blind. The red-blind had no perception of light coming from the distance through a red glass, while those who were green blind distinguished it perfectly. Red blindness appears to be somewhat more frequent than green blindness in England. The intelligence of the person had no connection with the color perception. It was hereditary. (*l. c.*)

Donders. *Color Blindness. An. d' Oc.*, Sept., 1881. *A. f. Ophth.*, Vol. xxvii. 1. The first part is principally historical. He argues against Hering's theory, and also for the separate condition of a red and a green blindness. There are four primary colors, red, yellow, green, blue, and 6000 color impressions.

Dor. *Perception of Colors.* "Intern. Med. Congr.," in London. *Arch. Ophthal.*, x, p. 339. The perception of colors takes place in the brain or optic nerve, but not in the retina.

Dor. *Concerning Our Knowledge of Daltonism.* "Intern. Ophth. Congr.," in Milan, p. 179. Discusses the priority of Holmgren's method. As early as 1859 he used a similar method, employing the same test colors. Since he did not publish it, Holmgren could not have known it. He rejects the classification into red, green, and violet blindness, and admits five kinds: total color blindness, red-green blindness, with normal or shortened spectrum; blue-yellow blindness, with normal or shortened spectrum. Holmgren's method is not a certain one. Rejects the Young-Helmholtz's theory. Delbœuf's cure for color blindness is in reality no cure. (*l. c.*)

De Fontenay. Om Faveansquesler. Hospitals Tidende, July 28, 1881. Recommends a systematic education of the color sense in school, and in his Kontrol Med. Faveblindheden. Hospitals Tinende, Sept. 14, 1881. He examined 2737 men, finding 3 per cent., and 502 women, with 0.6 per cent. of color blindness, in railroad employees. (See another paper by the same author, based on the examination of 9659 persons. *Archives Ophthal.*, Vol. x, p. 8, etc.)

Jâger. *Method of Educating and Developing the Color Sense. Natur*, No. 47. Recommends the system of Magnus. (*l. c.*)

Jeffries. *On Some Points in Regard to Color Blindness, Journ. of Nervous and Mental Disease*, July, 1881. Contests the assertion of Bannister, that color blindness can have no practical bearing in railroading, it being a well-known fact that color-blind people can perfectly distinguish colored signals. (*l. c.*)

Macé et Nicati. Contribution to the Study of the Visual Field, for Color. *A. d' Ophth.*, vol. 1, p. 506. A red, a green, and a blue glass is held successively before the eyes, and is determined how for a while a white piece of paper can be distinguished on the perimeter. The field for red is most contracted on gradually diminishing the intensity of light. Atrophy of the optic nerve and glaucoma show the narrowest field for red, by good illumination; and also the most pronounced reduction of central vision, when a red glass is held in front of the eye. In alcoholic amblyopia the central scotoma for red the most pronounced.

Pierd Hony. Une visite aliénée de la province à Mombello. Internat. Ophth. Congr. in Milan, p. 162. In Italy Daltonism is not so frequent as in Northern Europe. This is due to climatic and geographical influences, and also to the great vocabulary of words denoting colors. Among 900 insane persons there was not one case of Daltonism. Violet was the color, distinguished with most difficulty. A majority of those suffering from melancholia shrank from bright colors. (*loc. cit. W. C. Ayer's Transl.*) T.

Correspondence.

A Tedious Case of Labor.

Ed. Med. and Surg. Reporter:—

At 10 o'clock, P.M., Nov. 8th, I was called to attend Mrs. B., who was about to give birth to her fourth child. She is naturally a very large woman, and exceedingly fleshy, weighing about 300 pounds. I found her in considerable pain. The waters had escaped before my arrival. Upon making an examination I was thunderstruck to find how little work nature had done

to prepare this woman for labor. The vagina was small, its walls tense and hard, and the ordinary dilatation and relaxation of the parts *non est.* With much effort I made out to reach the os, and found it hard and but little dilated. Her pains were short and seldom. I made preparations to wait and see what the *vis naturæ* would do. From time to time I examined her during a pain, and at 1 o'clock, A.M, found the os dilated to about an inch and a half in diameter, through which I made out the presentation; head. The pains were now very severe and quite frequent, but of short duration.

I now sent for an old and experienced physician, Dr. Patton, of Skowhegan, who arrived at 4 A.M. He at once appreciated the gravity of the case, but said that he would like to wait awhile to see what progress was being made, before he adopted radical measures. We gave ether in sufficient quantities to make it easy for the patient. But time wore away and our patient was wearing out with pain and worry. The head had descended, face anterior, and was wedged up high behind the pubic bones. At my request Dr. Patton resorted to his forceps. He worked away for half an hour in an attempt to apply them. He could get them nearly placed when the head would slip away and we would have to wait for another pain to bring it back. Once or twice he made some traction, without having been able to lock the forceps, but to no purpose. The pains were feeble now and the woman moaning piteously, and the attendants and husband alarmed. I asked the Doctor to allow me to try the forceps, which he did. I gave his up and got my own, feeling that, being familiar with them I could apply them. Alas, it was not as easy as it appeared to be. But with hook and vectis I brought the head down where we could work better.

I now gave up the case to the Doctor and asked him to go ahead and I would assist, but did not wish to take the lead. After many attempts to deliver by the forceps, at 10 o'clock A.M., the Doctor called for my perforator and went to work with that. But the large skull seemed perfectly solid and no fontanelle could be found. Everything seemed wrong and now doctors, as well as the patient, were becoming exhausted. After an hour's work, after much boring, drilling, and turning, the thick skull parted and the instrument went into the cranial cavity. In a short time more we had the child. The cord broke off high up, and as I had the smallest hand I introduced my right hand into the uterus and delivered the after-birth. It was now nearly noon. The loss of blood was considerable, but not great. The child was a female and of large size and big head. There was one small fontanelle, but so small that it could not be detected only upon very close examination. I don't know how much the child weighed, as we could find no steelyards to weigh it and was not allowed to remove it from the house. I should think it safe to say 10 pounds. The head was very large, and the skull very thick, and the bones as well united as in a child a year old. I should never have got through with the case had it not been for the valuable aid rendered by Hon. S. A. Patten, M.D.

The woman, at this writing (Nov. 14th) is doing very well. Of course she is very sore and lame and on account of being so fleshy and heavy is hard to take care of and move. A few Dover's powders to insure rest, a mixture to guard against a rise of temperature and inflammation, and carbolic vaginal injections constitute all of the treatment up to the present time.

A. E. FARNHAM, M.D.

East Madison, Me., Nov. 14th, 1882.

NEWS AND MISCELLANY.

The Great Characteristic of Modern Medicine.

In the course of the Introductory Address at St. Thomas' Hospital, Mr. J. Seymour Sharkey said: "And now, gentlemen, if I were asked what is the great characteristic of modern medicine, I should say that it consisted in the union of anatomy, physiology, chemistry, physics, and pathology to form the compound science of medicine, and in the clear appreciation of their necessary inter-independence.

"There was a time, and that no so long ago, when most of these subjects were thought to have but little to do with the actual practice of our art; when physiology and pathology were talked of rather as subjects to be mastered by a few learned professors, to be more or less familiar to a certain number of leading practitioners, and to be all but ignored by the great mass of the profession. But things are so no longer."

Rides for Invalids.

From *The Boston Medical and Surgical Journal* we learn that a Boston Society engages itself in the work of providing free rides for invalids during the warm months. From last May to the present month 1343 persons were given rides. In addition, 1400 car tickets and 640 round tickets on the harbor steamers were distributed. A most excellent and wholesome charity, well worthy of imitation.

Cremation.

Dr. L. Ehrhart, a German physician, 75 years of age, of Allegheny City, was cremated in Dr. Le Moyne's furnace, at Washington, Pa., on Monday, Nov. 27th. This made the fifteenth cremation in the Le Moyne furnace, six of the bodies being from New York.

Items.

—The celebrated Prof. Friederich, in Heidelberg, died on the 6th of last month. His work on "Progressive Muscular Atrophy" belongs to those which make his name known the world over.

—Mr Clon Stephanos made several researches into the death rate in Greece during certain seasons, and has communicated to us the statistical results, which exactly correspond with the observations of Hippocrates on the same subject.

A Peculiar Case.

In Homer Bronson's garden, in Waterbury, was buried the arm he lost last August. He complained that the arm felt tired and cramped, but he experienced instant relief when, without his knowledge, the arm was exhumed and reinterred in a different position. Three times the severed limb has been moved, to give relief to the sufferer, and each time successfully.

The above we find reported in a reputable and reliable daily journal. An explanation we cannot give, but notice it in passing.

OBITUARY NOTICES.

PROF. HENRY DRAPER, M.D., LL.D.

Prof. Henry Draper died suddenly, in New York, Nov. 19th, 1882. Although only 45 years of age, he had already attained a foremost position in the scientific world. He was born in Prince Edward County, Va., his father being the distinguished chemist and physiologist. He graduated in medicine in 1858, and after a course of study in Europe, returned to New York and was attached to the staff of Bellevue Hospital. His predilection for scientific pursuits, however, induced him to relinquish the practice of his profession, although he occupied for some years the chair of Physiology in the medical department of the University of New York. He was a most enthusiastic astronomer, and perhaps his most remarkable achievement was the discovery of oxygen in the sun, which was made in 1877.

In 1872 Prof. Draper obtained a photograph of the diffraction spectrum, which has never been excelled. It comprised the region from below G. wave length 4350, to O, wave length 3440, on one plate. Small portions of the diffraction spectrum have since been taken on a larger scale, though none of them were veritable for determining the relative wave lengths of the fixed lines. Secchi, in his masterly work on the sun, used an illustration from this photograph of Prof. Draper's, and the British Association recognized its value by reproducing it and indorsing it as the best that had ever been taken. The transit of Venus, in 1874, afforded an exceptional opportunity for the display of perfected photography, and Prof. Draper, as its ablest exponent, was appointed superintendent of the photographic department by the commission which was sent out by this Government to observe the phenomenon. His work was so successful and so gratifying to scientific men, that it attracted the attention of Congress, which ordered a special gold medal to be struck off and presented to him. This was done, at the Philadelphia Mint. The memento bears the Latin inscription "Decori decus addit avito," "He adds lustre to ancestral glory." This was the first instance in the history of the United States, that any such public recognition was given by Congress to a scientist.

His death was due to a pleuritic affection, contracted a couple of months ago, when, on a visit to the Rocky Mountains, his party were caught in a severe storm. He was an ardent sportsman and very popular in a large social circle.

ISAAC B. MULFORD, M.D.,

died recently, at his residence in Camden, N. J., of paralysis of the heart. Dr. Mulford was born in Millville, N. J., in 1843, and was in the thirty-ninth year of his age. Entering the West Jersey Academy early in life, he completed his collegiate preparatory course at Monticello Institute, N. Y., and entered Princeton College in 1861, graduating with the degree of Bachelor of Arts in the Class of 1865. After the completion of the course at Princeton, he entered the Medical Department of the University of Pennsylvania, graduating as a Doctor of Medicine in 1870. Entering upon the practice of his profession in Camden, he soon gained the confidence and esteem of the community, and was regarded as one of the most cultured and successful physicians in Camden. He was a member of the Camden City Medical Society, ex-president of the Camden County Medical Society, member of the Medical Society of New Jersey, the New Jersey Sanitary Association, the American Academy of Medicine, the American Medical Association, and surgeon of the Sixth Regiment N. G., N. J. He was buried at Millville, N. J., on Friday.

DR. C. C. COX,

who had been successively Lieutenant-Governor of Maryland, Commissioner of Pensions, President of the Board of Health of the District of Columbia, and Commissioner to the Australian Exposition, died in Washington on Saturday night, Nov. 25th. He was a graduate of Yale College, and his literary attainments were considerable, some of his published poems having secured wide circulation. He leaves a widow, one son and a married daughter.

DR. JOHN S. WHILLDIN.

Advices from St. Paul, Minn., announce the sudden death, from heart disease, in that city, of Dr. John S. Whilldin, formerly of this city, and a son of Mr. Alexander Whilldin, the wool merchant. Dr. Whilldin was a graduate of the University of Pennsylvania.

QUERIES AND REPLIES.

S. D. P.—1. Puerperal fever is exceedingly contagious. 2. Yes. 3. No.

F. M. C.—Many articles and methods have been suggested to conceal the odor of iodoform. By reference to the REPORTER for April 29, 1882, p. 487, you will find what is probably the best.

MARRIAGES.

BATEMAN—LAWRENCE.—On Wednesday, Nov. 1st, by Rev. George L. Smith, E. R. Bateman, M.D. and Mary P. Lawrence, all of Cedarville, N. J.

BLAUVELT–DEDEREO.–On Thursday, Oct. 19th, at the residence of the bride's parents, Sparkill, N. Y., by Rev. W. C. Stitt, Gerritt Franklin Blauvelt, M.D., of Nyack, N. Y., and Julia Thompson, daughter of Isaac M. Dedereo.

DEATHS.

SANFORD.—At Ravenswood, L. Island, on Monday morning, Oct. 30th, 1882, Samuel T. W. Sanford, M.D.

TOWNSEND.—At Glen Cove, L. Island, on Monday, Oct. 30th, 1882, James C. Townsend, M.D., in the 86th year of his age.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations. Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA.

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

THE INFLUENCE OF CONSTITUTIONAL DIATHESES ON TRAUMATIC LESIONS.

BY M. PAUL RECLUS,

Professor Agregé of the Paris Faculty.

Gentlemen: Formerly the traumatism attracted the entire attention of the surgeon, and little attention was paid to any constitutional defects in the patient himself, in his surroundings or diet. It is true that it was proclaimed, as a matter of theory, that the diverse cachectic conditions retarded the cure of wounds, but practically the doctrine received little attention, except, perhaps, that it induced non-intervention in cases of anal fistula when the subject was in advanced phthisis. It would be impossible to find any memoir which treats of the influence of the constitutional condition on the course, evolution and issue of the malady. It is M. Verneuil who has undertaken this task, and has shown us, by numerous clinical facts, how any constitutional diathesis reacts on wounds.

We are now acquainted with the ordinary evolution of wounds in subjects affected with syphilis or alcoholism, diabetes or scrofula, malaria or rheumatism, and also with the manner a hidden diathesis may be awakened or revived through the perturbations induced in the system by the reception of a traumatism. Analysis has even been carried further; two diabetic conditions exist sometimes in the same subject; a drunkard may also be under the influence of malarial poisoning; syphilis may co-exist with phthisis, and certain facts prove that the wound or malady may be influenced in different degrees by the two diatheses. We already possess a thesis on syphilitic iritis in scrofulous subjects.

It is on this account that a traumatism may induce entirely different effects in different subjects.

An individual receives a blow on the testicle; if the organ is in a normal condition and the subject not under the influence of any well established diathesis, simple inflammation will occur: if he is scrofulous, cheesy masses will be deposited in the parenchyma of the organ, a veritable tuberculous orchitis supervening; if the individual is syphilitic, sclerosis or gumma may be formed; finally, a cancerous deposit may appear in an arthritic subject.

To explain these facts the terms "predisposition or idiosyncrasy" were formerly used, but are gradually being replaced by more precise notions: idiosyncrasy or predisposition merely point to some hidden diathesis which has, in a certain number of cases, been finally brought to light.

A well defined term now replaces the vague term under which the malady remained confounded with other constitutional conditions. Do we not know, for instance, that, after operations, the individuals "predisposed" to gangrenous inflammation are almost always diabetic? And this idea has become so thoroughly established, that even the most daring surgeons rarely undertake an operation of any importance without a preliminary analysis of the urine.

This research for any existing diathesis bids

fair to become of very great importance in the consideration of prognosis after operations.

To mention a case in point, I operated, in concurrence with M. Collin, who aided me in placing a suitable apparatus, in a case of talipes equinus, of paralytic origin.

Notwithstanding the greatest care, there supervened, at the point of the heel and over the head of the first and fifth metatarsal bones, a gangrenous eschar, which, fortunately, did not spread far or prevent ultimate cure, with an excellent result. To explain this localized gangrene, should we say that the patient was "predisposed?"

We recall the memoirs of MM. Verneuil and Nepven, on the trophic ulcers of limbs affected with infantile paralysis. In some of the cases they reported the muscles and integuments equally suffered, showing that operations on paralyzed limbs should be undertaken with great caution, for the skin cannot bear a pressure which would be of no danger for an individual in perfect health.

M. Verneuil has then substituted for the terms "predisposition and idiosyncrasy," certain very clear propositions. In his opinion: 1. The healthy individual may contract a multitude of lesions, affections or maladies; he is not specially predisposed to any of them. 2. The "predisposed" individual is one who presents in some part of the system an anatomical defect, affecting a tissue, an organ, a solid or a fluid, or a physiological disorder deranging some function or propriety of the economy; it is a subject who has been ill or is about to become so. 3. The predisposition is simply the defect, the disorder, the point of least resistance. It is the anterior condition, known or unknown, hidden or suspected, which, with the adjunction of some perturbing influence, will induce the appearance or reappearance of a lesion, an affection or a malady. 4. As a state of absolute good health is very rare, each individual has his predisposition, if he has not several. It is true that the predisposition may remain hidden if no great perturbation of the system bring it to light. 5. Predisposition thus considered presents nothing mysterious; it may be exceedingly difficult to divine its presence or demonstrate its existence, but not more so than to establish, in many cases, a satisfactory diagnosis. 6. Exact knowledge of a constitutional predisposition affords great aid for prophylaxis and treatment.

And this is not all; besides these constitutional states and diatheses there may exist certain local derangements which cause a tissue, an organ, an apparatus or a system to become what the ancients termed "a point of least resistance." This idea was long lost sight of, but its reality has been demonstrated by incontestable facts. It is well known that the local manifestations of certain general diseases do not affect indifferently any part of the organism; the points chosen are those already enfeebled by some anterior alteration.

A weak spot, the result of an old wound, may become, under the influence of a general disease supervening sooner or later after its cure, the starting point of a new affection.

It is thus that we have seen syphilis attack old cicatrices; cancer invade tumors that have long appeared benign; rheumatism attack joints formerly affected; scrofula a limb atrophied from infancy, and typhoid fever induce a fresh attack of osteitis in a bone formerly affected.

Since 1876, less than a year after the presentation of M. Verneuil's memoir at the medical congress at Nantes, I have essayed to demonstrate that the testicle is often, in tuberculosis, a point of least resistance.

In an individual whose constitution is otherwise good, the spermatic gland may, through diverse causes, become a favorable point for the development of tubercle, and a shock or blow incapable of affecting any other point of the organism may here induce a morbid deposit.

Out of 60 observations of tuberculous disease, we found that in 36 cases the lungs and the genito-urinary organs were simultaneously attacked, while in 24 cases the spermatic gland alone was affected, and that after a simple bruise, a blow, or under the influence of inflammation propagated from the urethra.

And does not the same hold true for syphilis of the testicle?

Even those who have been least preoccupied regarding this point of general pathology, bring their contingent of proof: "If, as they say, the testicle is the oftenest attacked, it is because the organ is fatigued by excesses, its tissues are not in proper condition to defend themselves, and syphilis finds in them a "point of least resistance."

According to Fournier, syphilitic sarcocele often results "from veritable overwork, violent and prolonged venereal excesses."

Syphilis has a special tendency to affect a testicle which has been the seat of anterior inflammation, such as gonorrhœal orchitis. "This is," says Ricord, "one of the most powerful causes of the development of syphilitic sarcocele. And in his opinion, the influence of anterior in-

flammation is such that the accidents may not follow their usual order of succession." There is a change in the course of the disease which, instead of commencing in the testicle itself, first attacks the epidermis."

Again, he says that it is only in cases where particular circumstances have acted on these organs that the tumor is developed.

The importance of M. Verneuil's researches can be readily understood. In reality, the etiology of a malady is a guide to its treatment, and every conquest in the domain of causation has, as a consequence, a like progress in therapeutics. Contemporary surgery should then have higher aims than the improvement of methods and the seeking for new methods of operating; it should seek particularly to avoid any operation "which is simply an expedient, a last resource, when nothing else can be thought of."

M. Verneuil particularly condemns those impatient and daring surgeons who, without establishing a precise diagnosis, perform operations which, from the nature of the circumstances, can have no favorable issue. The nature of the antiseptic dressings in use save them ordinarily from an immediate catastrophe, but what results do they hope to obtain?

And it would seem that it is not alone "the seekers of adventures" who wish to acquire éclat by the daring nature of their operations. A sort of "delirium for operations" seems to have attacked the entire generation of surgeons. At a recent medical congress in Germany, one surgeon reported having removed the entire larynx and a part of the trachea; another had removed also the tongue and pharynx; a third, a part of the œsophagus. Extirpation of the kidney, spleen, uterus, and resection of the stomach, colon and rectum were cited as of ordinary occurrence. And these operations were performed for cancerous tumors of rapid and fatal recurrence.

When a patient will necessarily die in a few days or a few months, is it justifiable to inflict such mutilations, which sometimes cause his death during or just after the operation?

If such was the only danger from this fury for operations, the lives of a few unhappy beings would be shortened, and that is all.

But detestable habits are thus acquired; the case is not properly studied, and no clear diagnosis is arrived at. The tumors are not even studied as to whether they should be removed or not. They are, first of all, extirpated; it is then for the pathologist in his laboratory to determine their nature, malignant or otherwise.

But, if the excessive zeal of the surgeons of our day is to be condemned, it must be said that ordinary therapeutic measures accomplish little. The surgeons do too much and the physicians too little. These last show a lamentable indifference in the treatment of neoplasms; they are satisfied in prescribing, intus et extra, the inevitable iodide of potash and arsenic, which is no doubt of advantage, but leads no further toward cure than the other.

"Under such circumstances, instead of falling into despair with the fatalists, why should we not seek for indications for treatment at the only source which can furnish them, that is, in etiologic studies? Why reproduce again and again the same old doctrines on the origin of cancer and similar products, instead of utilizing and verifying the important idea that the true neoplasm derived its origin directly from arthritism." (Verneuil.)

You well remember the views of M. Bouchard, who demonstrated that slowing-up of nutrition or bradytrophy is a primary factor in the causation of the arthritic condition of the system, of which the most ordinary manifestations are gout, obesity, biliary lithiasis, gravel and saccharine diabetes. Perhaps cancer could also be included in this list, but the ideas of M. Verneuil on the subject are not so generally admitted as he may believe; he has long affirmed that cancer has its origin in the arthritic diathesis, but clear proofs of the assertion are still wanting.

However, as he himself remarks, in the introduction to his memoir, "with this view of the origin of cancer there might remain some hope of one day arriving at means for its prevention and cure. There would be some attempt to combat and destroy this neoplasm of arthritic origin, just as we at present prevent, combat and destroy the neoplasm of syphilitic origin which was formerly removed by the bistoury; as we cure also the simple inflammatory neoplasm, and in certain cases the morbid product of strumous origin, by favoring the cheesy or fibroid metamorphosis of the tubercle."

Amputation at the Hip-joint.

The *British Med. Jour.* says that two cases of amputation at the hip-joint were performed at the South Devon Hospital during August. The first case, by Mr. Paul Swain, for exhausting suppuration of the limb, is quite convalescent. The second, by Mr. Square, for rapidly growing malignant tumor of the shaft of the femur, in a man aged 19, is progressing favorably towards recovery. In both cases, Davy's lever was used to control the artery, with success.

Communications.

A PLEA FOR MILDER MEDICATION AND GENTLER MANIPULATION IN THE TREATMENT OF URETHRITIS, ACUTE AND CHRONIC.

BY JOSEPH H. WARREN, A.M., M.D.,

Physician to Massachusetts Home for Intemperate Women, Boston.

Many cases of acute gonorrhœa, through neglect or bad treatment, pass into a chronic urethritis, characterized by more or less pain, tenderness, and a muco-purulent urethral discharge. If this is allowed to continue it finally passes into the chronic affection known as gleet. The tissue usually involved is the urethral mucous membrane, especially in the vicinity of the lacunæ of the fossa navicularis and of the bulb.

But the inflammation may not stop here; it may progress until it has involved, in the male, not only the bladder, but also the prostate gland and the testes. In the female the clitoris and the vaginal mucous membrane may be affected, and then the inflammation may attack the cervix of the uterus, and if still further neglected, may involve the fundus and extend up the Fallopian tubes even to the ovaries. More than this, I think it will be found the inflammatory process may invade tissues deeper than the superficial mucous membranes, until finally the submucous tissues ulcerate and melt away by suppuration.

This state of things follows a simple gonorrhœa much more frequently than many of the profession generally suppose. As soon as the patient is relieved of the inconvenience of the burning and the smarting pains during or after micturition, and of the thick, purulent discharge from the urethra, nothing is simpler than for him to trust to good luck for his final cure. Possibly, however, he may consult his friend, the prescribing apothecary, and be assured that his gonorrhœa is cured and that the gleet will take care of itself.

When these patients come to us for treatment at a period varying from fifteen days to three months, or later even, after the beginning of their gonorrhœa, the question of how we shall best succeed in giving relief is a very important one. If the case has been progressing some length of time we shall find, upon external examination, considerable tenderness to the touch all along the urethral tract, and particularly at the bulb and within an inch of the glans.

Upon passing the sound we find considerable urethral irritation, and usually one or more contractions or strictures. These strictures, in most cases, can and should be overcome by the repeated passage of bulbous bougies. For this operation I am greatly pleased, as well as some other prominent men in the profession, with my vermicular sound, here figured. The reader, however, can gain from the figure only an imperfect idea of their shape, of the comfort, both to patient and operator in their use, and of their good and satisfactory results in the treatment of urethral strictures. These sounds, of various sizes, are made very finely by Geo. Tiemann & Co., of New York city. The bulb is fastened on a German silver staff, so it can be bent to any desired curve.

After dipping the sound into carbolized cosmoline I usually powder over it iodoform, which is carried along the urethral canal by the partially grooved vermicular tip and deposited for the most part at the seat of the obstruction. During the treatment by dilatation I order the patient to take quin. sulph., gr. v, t. i. d. before meals, to be followed by sodii brom., gr. x–xv. I might here say that in my practice I have found the bromide and the carbonate of soda to be almost a specific for irritations of the urethra and the uterus. At night I order the following urethral suppository to be used: —

℞. Iodoformi,	gr. xx	
Ac. tannici,	gr. x	
Ol. theobromæ,	q. s.	M.

Ft. suppos. urethr. No. x.

In the meantime the bowels should be kept freely open with some saline mixture, or with a teaspoonful of pulv. glycyrrhizæ comp. at night. If the inflammation is very active, the patient should be directed to procure some small rubber tubing, say an eighth or quarter of an inch in diameter, and slit down one end for about half an inch, in order to introduce it the more readily into the urethra. Now, take a gallon or two of water, as hot as can easily be borne, and bathe the urethra; and a few ounces, if necessary, can be thrown, by means of a catheter attached to the tubing, into the bladder; the bladder should be thoroughly washed out by making a siphon of the tubing. This douche may be repeated as often daily as is agreeable to the patient. Instead of clear water, a weak solution of the tannate of lead will often be found a very soothing application; twenty grains to the quart is the most suitable in the largest number of cases. Many cases that I formerly thought impossible to divide or dilate I

now divide with the Cook's (?) knife, which consists of a long, slender shank containing a blade that can be pushed out at the side. This is more convenient than the most of such instruments, because the amount of cutting edge displayed can be more easily gauged by the operator than with the common urethrotome; in my hands, at least, I find it so, with but few exceptions. Many old chronic cases, like two that I have now under treatment, experience great relief from gleet and the various sequelæ of gonorrhœa, such, for example, as gonorrhœal rheumatism, by the use of the urethral suppositories at night, the hot douche in the morning, and the following prescription night and morning:—

℞. Ac. salicylic, gr. x
Sodii brom., gr. xv. M.

One of these patients to whom I have referred had been treated for three years by different physicians, for some kidney affection, has taken iron and quinine for general tonics, and yet, six weeks ago, he could not attend to his business as a merchant for more than a few hours a day. Under the treatment which I have described above for such cases, he says he is now as well and strong as ever in his life.

In some of these cases there is more or less swelling and tenderness of the testicles and spermatic cord, and often cystitis, dyspepsia and hypochondriasis. These symptoms may often be removed by adding sodii hyposulphide, ℥j to each gallon of the hot water employed in the douches, and at same time taking a wineglassful of this solution after meals. This same salt, in a more concentrated solution, will be found very advantageous in the treatment of vaginitis and acute urethritis, and it has the recommendation of being cheap and not staining clothing. I speak from a long experience in the use of this salt; and some twenty years ago I wrote an article in the Boston *Medical and Surgical Journal*, on the use of the salt in inflammatory rheumatism; and I have also found it useful in relieving the distress of cicatrices from burns. I am afraid, however, that, owing to its cheapness, it, like Glauber's salts, for example, is discarded for more expensive but no more efficient drugs.

In conclusion, I ask myself if, in the treatment of acute gonorrhœa, we do not resort too hastily to over treatment with copaiba, cubebs, injections of zinc sulphate, nitrate of silver, fl. ext. hydrastis canadensis, and thus bring upon the patient many of the sequelæ so often seen. Gonorrhœa is a local disease, but when neglected it may lead to all the affections above named, and even to far more severe constitutional disturbances. I think it can be readily cured by the frequent injection of tepid water, and the internal administration of sodæ bicarb., or bromide of soda, with mild demulcent drinks, such as that made of medulla, sassafras, linum, or flaxseed, barley, or quince seed; we can add to these agents, to allay painful erections, morphia in syrup tolu, aq. camphor, ether nit., or spirits ether comp.; cosmoline, with two and a half grains of ext. belladonna, or one-eighth of a grain of sulph. atropia, to the ounce, applied freely about the parts, will generally give comfort and ease to our patients, with results far more satisfactory to all, and less of the sequelæ so numerous with the more heroic and hasty methods much in vogue, I have already mentioned. Besides, I think the sound is passed, in many cases, too early in the acute stage of the disease. Although the use of the sound is a very valuable agent to be employed for the cure of this affection, it should be used with caution, and at the proper stage of the disease. I have seen fearful results follow the careless use of the sound. I have for years given my patients, the night before passing the sound, opii, with a full dose of sulph. quinia, as a caution of safety, and to lessen the complications so apt to follow without such precautions.

VERNEUIL'S MODIFICATION OF AMUSSAT'S OPERATION FOR THE RELIEF OF IMPERFORATE RECTUM.

BY WILLIAM A. BYRD, M.D.,
Of Quincy, Illinois.

At the meeting of the Tri-States Medical Society, in St. Louis, in 1881, I read a paper on "Lumbo-Colotomy in the new-born, for relief of imperforate anus," that has been pretty generally abstracted in the medical journals, and fairly represented in Dr. C. B. Kelsey's excellent book on "Diseases of the Rectum and Anus." The plan there described I believed to be more applicable to cases presenting like difficulties than any other so far designed; but there are cases in which the distended *cul de sac* of the rectum may be felt slightly fluctuating by passing the finger within the rudimentary anus; such, I believe, will be more successfully treated by the method named as the title of this paper.

Dr. Van Buren, in his work on "Diseases of the Rectum," 2d ed., p. 372, states, "Amussat, in the year 1835, devised the novel resource of dragging down the upper rectal cul-de-sac and stitching it to the edges of the perineal opening, thereby establishing a canal continuously lined by mucous membrane, and, consequently,

free from danger of contraction;" then, on page 373 he says, "By way of enlarging the external opening, so as to aid in finding and detaching the rectal pouch, Prof. Verneuil, of Paris, has exsected the coccyx in several instances, and speaks well of this addition to Amussat's operation, as enabling him to advance more readily along the concavity of the sacrum."

Aug. 29th, 1882, I was called, with Dr. M. Rooney, to see Henry T., a child four days old, that had imperforate rectum. The child was very small and feeble, not having had more than eight months of uterine existence. Owing to its feeble condition the parents objected to having any operation performed for its relief, although all the physicians present, among them Dr. J. H. Ledlie, of Pittsfield, Illinois, strongly advised it. The next day we were sent for, the parents having decided, after talking to their preacher, that it was better that some effort should be made, than allow it to die miserably without it. So, in the afternoon, assisted by Drs. M. and A. L. F. Rooney, Henry Hatch and E. B. Montgomery, the operation was performed. There was a rudimentary anus nearly half an inch deep. The incision was made within it at the front, extending back about an inch, and about an inch in depth. The pelvis being very narrow, and wishing more room, so as to avoid the possibility of wounding the bladder or the ureters, I cut away the entire coccyx, which permitted the incision to be easily made an inch deeper, when the dark gray pouch of the rectum filled with meconium came into view. This was now dragged down and the end cut off and the edges stitched into the part of the cut where the anus should have been, with several fine catgut sutures. The child made an excellent recovery, is growing rapidly, and is now in robust health.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. Seelye, A.M., M.D.

Hemiplegia.

The patient was admitted to the hospital on Oct. 3d, 1881. His name is J. P. Age, 55. Nationality, Swedish. Is unmarried. Has been a sailor for the past twenty-five years, and so was much exposed to rough weather. Is also an old drinker. Until within the last two months he has been perfectly healthy for the past twenty years. Before that he had an attack of rheumatism in the ankles, which lasted three weeks. Has also had the clap. Two months ago he began to have a dull, heavy feeling in his head, and was troubled with vertigo. About three weeks ago he went to bed feeling as usual, but in the morning when he awoke he experienced a peculiar sensation in his right arm and leg, and found that he could not move them. On attempting to speak, he could not articulate well, nor say what he wanted to. It has been difficult for him to talk, and his speech has been thick and imperfect since then, but is now much improved. He is also able to walk now, but he drags his right leg behind him, and it scrapes along the floor. His bowels have been normal in action, and his appetite good.

Gentlemen, I wish you to notice the method followed in these histories which you hear read here. For it is a great accomplishment to be able to take a good history. The traditions of this hospital regarding this matter are, I think, admirable. It embraces, in a few words, the noting down briefly the patient's previous history, and his age, sex, nationality, condition in life, occupation, habits, family history, and the history of any previous illnesses which may bear upon the history of the present trouble. The age, sex and condition of the patient often have much to do with the nature of the disease, and the hereditary history is the most important of all.

Having now heard the subjective history of this patient, I need not ask you as to the nature of his malady. He has, in a word, hemiplegia. Now what shall we examine for, in a case of hemiplegia? Obviously we will first look for the causes of the disturbance in the power of motion.

Inspection.—We see nothing about the facial muscles in this case to especially attract our attention. But I notice a slight dropping down of the right side of the face, and the right corner of the mouth is a little lower than the left. He uses the orbicularis oris and buccinator muscles well, however, and is able to whistle. So far as the face is concerned, there is no appearance of paralysis. He can raise his right arm slowly and can flex the elbow. His grasping power with his right hand is very feeble, but he has a strong grip with his left. In walking he drags his right foot, and there is evidently a considerable loss of power. In cases of this kind it is often desirable to estimate the loss of muscular power as accurately as possible, and for this purpose we have an instrument called the dynamometer, by which we can test in pounds the strength of any part. It consists essentially of a spring, a needle, and a scale marked off in pounds, numbering in this case from ten to ninety-five. On testing this man we find that with his right hand he scarcely moves the index, but with his left he sends the needle around to nearly its whole extent. So here we have demonstrated accurately the difference in power on the two sides of the body. Next we will investigate the function of sensibility. This we can do roughly by pulling the hair, or pinching or pricking the skin, but more accurately by the use of the æsthesiometer. Examining this man thus, we find that there is no difference in sensibility of the two sides of the face, and there is but slight loss of sensibility in the right hand as compared with the left. It is often the case in hemiplegia, that there is little or no loss of sensibility. This man does not see double, and

there is no disturbance of vision. There are still other symptoms in hemiplegia, for which it is important to examine. We should test the electrical sensibility of the muscles, and look for any spasmodic movements, or for clonic or tonic spasms of the muscles. This man's joints are all flexible, so it is certain that he has no tonic spasms or cramps.

We now come to the investigation of the most important element in this case. You remember he awoke one morning with loss of speech, and he could only mumble his words. Now he has somewhat recovered, and on asking him questions he gives intelligent answers, and makes a correct selection of his words, but he repeats them slowly and with some difficulty of articulation. He has not, therefore, amnesic aphasia. He cannot pronounce the letter "V" correctly, but says "We" instead, and "wine" for "vine." There is, therefore, still a certain amount of incoördination of the muscles necessary to pronounce certain letters. This general loss of power was first noticed on the twenty-sixth of September, and now, on the seventeenth of October, he has gained considerable power in both his upper and lower extremities, and his speech is very much improved.

In considering the causes of hemiplegia it is important to examine the heart, arteries and kidneys, and their functions. But we will not linger longer on this case now, but will consider these and other points in connection with the next case, which is one of similar character.

Case 2.—This patient was admitted to the hospital on Oct. 13th. Name Wm. M.; age 36; nationality United States; occupation printer; is unmarried. Four days ago he was found lying in bed, speechless, and paralyzed on the right side; and he was brought here in that condition. He has remained so ever since, with no improvement.

One of the students was now called down into the amphitheatre to examine the case, and the following symptoms were noticed: The muscles of the face and eyes were normal in action. When the eyes were shaded and uncovered alternately, it was found that the left pupil did not respond to the light as well as the right, and it was slightly dilated. When the tongue was protruded it deviated slightly to the right side. The arms and legs were flexible, and there was no rigidity of any of the muscles. The surface sensibility was about normal. The right hand moved the dynamometer index needle only about two pounds; the left hand, eighty pounds. He was able to raise the right leg from the bed and move it freely. This man being dumb, and not so clear in his mind as the other patient, it is not so easy to get much information from him. Another important point in the examination is, to test the power of reflex excitability. As a rule, in hemiplegia this is not seriously disturbed, because the lesion is high up in the cerebrum, while the spinal cord is usually left intact. On tickling this man's feet we find no exalted reflex sensibility here. When asked his name he tries to tell it, but cannot, but repeats "name, name," several times. And so with other questions; he cannot use the word that he wishes to, though he knows what he wants to say; for when asked how many brothers he has, he counts off three on his fingers. Sometimes these patients also lose the power of gesticulation, and cannot even write their own name, though they know what it is, perfectly well. Where the aphasia is simply due to incoördination of the muscles of speech, it is called ataxic. But where the memory of words is lost, it is called amnesic aphasia. Both may be present in the same patient. This man has the ataxic form, and probably the amnesic also, to some extent, though it is not easy to say certainly.

His arteries are felt to be slightly rigid or stiff, but not markedly so. The heart sounds are natural and the position of the apex beat normal, as is also the area of percussion dullness. So there is no cardiac hypertrophy. The urine is negative. In the first patient the heart and the urine are normal, but the arteries are decidedly stiffened, showing some atheromatous degeneration.

Gentlemen, you have now seen two cases of right hemiplegia, and observed certain likenesses in the symptoms of the two patients. The first patient is recovering from his aphasia, while the second is still affected to a considerable degree. He has not the power to say "yes" or "no."

In considering the causes of hemiplegia, we must distinguish between an attack with a sudden onset, and one of slow occurrence. A sudden attack may be due to either cerebral embolism, hemorrhage, or thrombosis; or it may sometimes follow an epileptic seizure, in which the symptoms are generally more marked on one side than the other, and there is usually a transient loss of power. The explanation of these epileptic cases is not thoroughly understood. Some say that the attack is due to the sudden constriction of the blood vessels, thus causing an anæmia of the brain; others, that it is caused by the exhaustion after a great and sudden expenditure of nervous energy. Hemiplegia is sometimes seen in hysteria, though it is rare as compared with loss of power in certain groups of muscles, as those of the leg, arm, etc. We can usually distinguish these cases by the fact that they are generally anæsthetic on the side where there is loss of power.

In cases of hemiplegia the diagnosis must be more accurate in these days than formerly. Then, if a man suddenly fell down, and was found to be paralyzed on one side, it was always referred to apoplexy or hemorrhage. Within the last fifty years the causes have been carefully investigated, and now the diagnosis of the exact location of the lesion is one of the most interesting problems of medicine. I will leave you to ascertain for yourselves the locations where hemorrhage and embolism are most likely to occur, and to study up the symptoms which may follow hemorrhage into the brain. My object here is not to tell you all about this affection, but only to say enough to excite your interest in studying up the subject of hemiplegia, and the location of the lesion which causes it. The lesion in these patients is on the left side of the brain, and in the region of the speech centre and motor tract, which is located behind the third frontal convolution, in the vicinity of the island of Reil, and in the parts supplied by the middle cerebral artery.

It is difficult to distinguish paralysis due to embolism from that caused by cerebral hemorrhage. But there is one condition, which, if present, renders the diagnosis of embolism prob able, and that is valvular disease of the heart. The vegetations which form on the heart's valves are liable to become detached and so cause an embolism. This old man would be more likely to have a hemorrhage. The younger patient might have an embolism, but as he has never had rheumatism or heart disease, by exclusion we arrive at the probable diagnosis of hemorrhage on the left side of the brain. It may be located in the corpus striatum, which is the most frequent seat of hemorrhage. The optic thalamus is probably not involved, because there is such slight loss of sensation. It may also be in the white substance of the brain outside of these localities, or even in the gray matter of the convolutions. Wherever it may be, I do not think that the clot is very large in the case of the first patient, for improvement has been tolerably rapid thus far, and so he will probably recover his powers to a considerable extent. The other patient, having been here only four or five days, I cannot say how rapid the improvement will be in his case. He already has some use of his lower limb, which is usually the first to recover. The loss of speech here is so complete that the prognosis for the aphasia is very poor.

UNIVERSITY OF THE CITY OF NEW YORK.

CLINICAL LECTURE BY ALFRED C. POST, M.D., LL.D.

Professor Emeritus of Clinical Surgery.

GENTLEMEN:—This patient, æt. 65 years, about six weeks ago received a blow upon the shoulder, which afterward was said to be dislocated. Dislocation of the shoulder from a blow is of rare occurrence. The patient was under the influence of alcohol at the time, and his recollection of what happened is not very distinct, and it is probable he fell. If the shoulder was dislocated it has been reduced since, for there is no sign of dislocation at present. On comparing the two shoulders with each other, you can see that there is about the same amount of fullness or the same rotundity about both joints. If there were a dislocation downward into the axilla, or a sub-glenoid dislocation, as it is called, you would find the sharp prominence of the acromion very conspicuous. There would be a depression beneath it, into which you could lay two or three fingers, and by putting your finger into the axilla you could feel the head of the bone in its abnormal situation. There may be three other dislocations of this joint. Two of which are complete and the other incomplete. Of the two complete dislocations, one is forward under the pectoral muscle, sometimes called dislocation under the clavicle; and the other, which occurs very rarely, is a dislocation in which the head of the humerus is thrown backward on the scapula. But in all of these cases the abnormal position of the bone is quite conspicuous, and you observe the sharp prominence of the acromion and the hollow beneath it, and the want of fullness and rotundity which exists in the normal condition. It is clear, then, that if this patient has had a dislocation it has been reduced, and has remained reduced. You know that dislocation of the shoulder, when reduced, often recurs. A very slight accident will repeat the dislocation. A patient was at our clinic last Saturday, in whom a dislocation at the shoulder had recurred five times because it had not been properly secured in the first instance. There is this peculiarity about relapsing dislocations, that you can very easily reduce them. You will remember that in that case I did not etherize the patient, simply put my knee in the axilla, took hold of his arm and reduced the dislocation without any difficulty. That cannot ordinarily be done in dislocation in the first instance.

The patient complains of a little pain in the middle space, between the shoulder and the elbow, and there is a little discoloration of the integument here, which may be the remains of an ecchymosis which occurred at the time of the accident, six weeks ago. It takes a considerable time before a discoloration from an effusion of blood into the subcutaneous tissue entirely subsides. Here is also a little lump, perhaps due to a slight effusion beneath the periosteum. It is probably a matter of no consequence. Such a nodosity might indicate the seat of a fracture which had occurred at some previous time, but he says he has had no fracture. If such a nodosity had occurred upon one of the more superficial bones, as upon the tibia or the ulna, it would very naturally excite a suspicion of syphilitic disease. It is not very common, however, for a deeply situated bone, like the humerus, to be the seat of nodosities from that cause.

There has been, from the same injury, some inflammatory swelling about the hand. Exactly how that was brought about the patient is not able to give a strict account. He has been painting it with iodine and applying passive motion, and he says it is better than it was a week or two ago. After making passive motion the swelling becomes greater. That is an indication that the passive motion is carried too far. As a general rule, the error is on the other side; the patient does not usually make sufficient passive motion, because it hurts him at the time. Whenever passive motion simply gives pain at the time it is made, but does not afterward produce increased swelling, and whenever the rigidity of the parts gradually diminishes under its influence, you may know it is doing good, and is not being carried too far. However much pain may be given at the time, it does not contra-indicate a continuance of passive motion, unless there is increased swelling and heat of the part afterward. The patient may continue the treatment which he has been applying.

CASE 2.—It appears that this patient, aged 53 years, was raising a heavy iron bar, and it fell upon his shoulder, causing a severe contusion over the clavicle, very near the situation of the coraco-clavicular ligaments. You know that that ligamentous mass is composed of two bundles of fibres, which are described together under the name of coraco-clavicular ligaments, or under the two distinct names of conoid ligament and trapezoid ligament, both of which pass from the clavicle down to the coracoid process.

The probability is, from the continuance of the

pain and the tenderness for a fortnight after the injury, that there has been a fracture at that point. The clavicle, with reference to fractures, is divided into three regions. The first region extends from the sternal articulation of the clavicle to the inner side of the coraco-clavicular ligament, and whenever fracture occurs in this region, as a rule, the internal fragment, that connected with the sternum, lies upward; the external fragment, that connected with the acromion process, is depressed; the fragments override each other; when, however, the fracture occurs between those two ligamentous bands, both fragments are supported by ligaments passing down from the coracoid process, and scarcely any displacement occurs. The only displacement which takes place is a slight tilting up of the fractured end of the fragments, and a fracture occurring in that region is quite difficult to detect. It is not a matter of much importance if it is overlooked, for there is no apparatus which you can apply that will support the fragments and retain them in that position so well as these ligaments. I think it is probable that accident has occurred here, but it is not an easy matter to determine, a fortnight after, that it has occurred. When it was quite recent we might perhaps have detected, on careful examination, slight crepitus. No special treatment is called for in this case.

Case 3.—This little child has been here before, and is undergoing treatment for club-foot, the variety known as talipes varus. We will readjust the felt splint, the adhesive plaster and the bandage. I like this method of treating infantile club-foot much better than any of the spring shoes which are made for the purpose, for the latter are much more complicated and troublesome, and I do not think they accomplish the purpose as well.

Case 4.—This young man has a roseolar dermatitis on the outside portion of the leg, just below the knee, which has existed the last four weeks. His tongue is furred, and his face is flushed. These cutaneous inflammations are very apt to be associated with some disturbance of the digestive function, as seems to be the case with this patient. His bowels are also constipated. The main treatment should be directed to the condition of the digestive organs and general health. I think he will probably be benefitted by the use of a laxative pill, of which the following is the composition:—

℞.	Pulv. rhei.,		
	Soda bicarb.,	āā	ʒij
	Pulv. ipecac,		gr. xv
	Syr. zingiber,	q.s.	ut.

Let this mass be divided into forty pills, and take one pill three times a day, and it will generally produce a more healthy condition of the gastro-intestinal mucous membrane. This combination was introduced a good many years ago by Dr. Bulkley, the father of the present well-known dermatologist, Dr. L. D. Bulkley.

Case 5.—This woman, age 45 years, received a sprain of the ankle fourteen weeks ago. The term sprain is applied to an injury in which the fibrous tissues of a joint are put forcibly on the stretch, and in the severer cases some of these fibres are lacerated or ruptured. This accident may occur about any of the joints, but it is of very frequent occurrence about the ankle and the wrist joints, and although there is no very marked visible change in the parts which have been injured, the injury is often a more serious one than fracture of the bone of the leg or of the forearm. That is, it takes a longer time before the parts are restored to their normal condition. The immediate effects of a fracture are more severe, but the symptoms produced by a sprain may continue for a longer time, and will cause more serious trouble to the patient.

There is no visible change about the ankle in this case, except a little swelling about the sides of the joint, and there is pain and tenderness on pressure and on moving the joint. It is very important that you understand the proper manner of managing these joints, according to whether you see the case early or at a subsequent period. In the case of a very recent sprain anywhere, the patient should be kept for a few days at rest, with the part a little elevated, and if you see the patient very early, before any swelling has taken place, you may with advantage bandage the part so as to give equitable support. If an india-rubber bandage is carefully applied, not so as to restrain the circulation too much, but so as to make equal pressure on the part, it will prevent effusion into the tissues and swelling about the joint. If you do not see the patient until after the lapse of several hours, when there has been subcutaneous effusion of blood and an effusion of plastic lymph, you will find that cloths wrung out of hot water, water at a temperature of about 115° to 120° F., though uncomfortable to you will not be uncomfortable to the patient, except perhaps for an instant. There is a great difference between the effect of water considerably above blood heat and water at or below blood heat. Warm applications tend to relax the parts and to increase the flow of blood about the injured parts, while hot applications at a temperature of 115° or 120° have a tendency to constringe the vessels and to diminish the flow of blood to the parts. This is a very common practice now, in stopping hemorrhage, such as occurs in gynæcological practice. The hot water applications will stop the excessive determination of blood to the part without giving rise to inflammatory swelling.

At a later period, however, when active inflammation has begun to subside, the parts still remaining painful and tender on motion, it is not well to yield too much to the sensations of the patient. A moderate amount of exercise should be taken, and passive motion should be applied, in order to restore mobility to the joint and prevent rigidity from occurring. Although it may give pain at the time, the patient will recover much more rapidly than if the parts be too much nursed. It has been observed that injuries of this kind occurring in persons who are obliged to work are much less protracted in their effect than in persons who are entirely at leisure, and can nurse the limb for a long time. You will find that a person who is actively at work will get well in a few weeks, while a person who nurses the injured limb may suffer for months or even for years. Of course, you are to regulate

the amount of exercise, either active or passive, according to its effects, as was indicated in the previous case.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

Suppuration of the Middle Ear.

Read before the Association Nov. 10th, 1882, by Dr. J. G. Heilman.

The middle ear is an irregular cavity situated within the petrous bone. It is bounded exter nally by the membrana tympani and meatus; internally by the outer surface of the internal ear; it communicates behind with the mastoid cells; and in front with the Eustachian tube and canal for the tensor tympani muscle. Its roof and floor are formed by thin osseous laminæ, which connect the squamous and the petrous portions of the temporal bone. This cavity measures nearly half an inch from before backward, a fourth of an inch vertically and a little transversely. It is filled with air and traversed by a chain of movable bones which connect the membrana tympani with the labyrinth. These bones serve to transmit the vibrations communicated to the tympanic membrane across the cavity of the tympanum to the internal ear. It is lined with mucous membrane, as are also the Eustachian tube and mastoid cells.

From the frequent and often sudden changes in the density and temperature of the air filling this cavity, as well as its close connection with the throat, whose numerous catarrhal affections often extend into and through the Eustachian tube, we should naturally expect to find it frequently the seat of disease. Such is found to be the case by those who have given the subject attention. We shall at this time consider but one of these affections—suppuration. The importance of the subject becomes apparent when we consider the exceedingly offensive character of the purulent secretion from this cavity, the impairment of hearing that must necessarily follow an extensive destruction of tissue in this organ, *the constant danger that the suppurative process may extend into the brain* and thus destroy life, and the fact that by simple, judicious and intelligent treatment nearly all of these cases can be cured before any great amount of mischief has been done. The records of the Eye and Ear Department of the Philadelphia Dispensary show that cases rarely go on to the chronic stage when brought under its care early in the acute stage. On the other hand, by far the larger number of those who apply for treatment at our dispensaries, or at the office of the specialist, are chronic cases that have become such through neglect or want of properly directed treatment. A "running ear" is considered by the laity a matter of such trivial moment that in many cases it is deemed unnecessary to take professional advice. The usual history of such cases is about as follows: After a few days of intense earache, during which the patient, usually a child, has introduced into the external meatus a variety of substances (every one of which has cured some friend or neighbor) such as red pepper, hot lard, hot molasses, chamomile flowers, tobacco, onions, sweet oil and laudanum, chloroform, etc., etc., no relief follows and the family physician is called in, who, too often, according to routine, prescribes an opiate and *directs* the ear to be syringed with warm water and Castile soap. The drum being greatly inflamed and exceedingly sensitive, the stream of water often thrown with great force against it produces such intense suffering that this part of the treatment, after a few ineffectual attempts, is abandoned by the parents. After some days, or perhaps weeks, of suffering, the case passes through the subacute into the chronic stage. The pain has now subsided, but the discharge continues, and becoming offensive, the physician is again consulted, and, for a longer or shorter period, according to the amount of confidence reposed in him, and the financial ability and liberality of the family, he treats the case, until, having exhausted all his and most of their resources, he gives them the consoling information that the child will outgrow it. The child grows, and so does the disease; the hearing becomes more and more impaired, and the suppuration more and more profuse and offensive. In school other children refuse to sit near him, and he is now taken to some dispensary for treatment. This is the condition and the history presented by a large proportion of the cases that have come under my care at the Philadelphia Dispensary.

The causes of this affection are numerous. The following are the most common: cold air or water through the Eustachian tube or through a previous perforation of the drum, bathing in the ocean, diving, general exposure to cold, the nasal douche, dentition, puncture of the membrane by hair pin, match, etc. It is also a sequel of a number of diseases, as scarlet fever, whooping cough, measles, diphtheria. Of the latter, scarlatina is by far the most frequent cause.

The following are among the most prominent symptoms: the patient may complain of a soreness in the throat, which after a few days or hours extends to the ears. Sometimes the first symptom noticed is a sense of fullness or "stopped up" feeling in the affected ear; this is followed by a decided pain of an intermittent character, generally worse at night. There is fever and the tongue is furred. There is usually a slight chill when pus is forming. The pain now increases in intensity, the accumulation of pus in the tympanic cavity prevents the free transmission of sound, and the hearing, which in the stage of hyperæmia was morbidly acute, is almost lost; tinnitus is almost always present. After a variable period a discharge commences, at first a faint moisture, then a cream-like fluid, and at last an abundant purulent excretion. As soon as a free discharge is established the pain usually subsides and, except during acute exacerbations, is entirely absent in the chronic stage. In some cases exuberant granulations appear and fill up almost the entire cavity of the middle ear. In many cases the ossicles are separated by the destruction of their ligaments, and are discharged with the pus. Necrosis of the bony walls of the mastoid sometimes occur, and portions of these bones are discharged through the external canal. In one case under my care the outer wall of the

mastoid process was completely necrosed away and the cells destroyed, so that a cavity remained behind the ear about as large as a pigeon's egg. The patient when last seen was in a very good general condition, but, of course, his hearing on that side was lost.

The diagnosis in cases old enough to direct attention to the seat of pain is generally easy, but in young children the disease is often overlooked until the discharge appears. When a child persistenly screams and is feverish, it is well, before pronouncing it colic, to examine the ears. If there is inflammation of either external or middle ear, a little pressure over the antetragus will usually reveal it by the pain which it elicits. When the discharge appears there is no longer any doubt as to the nature or location of the disease.

The prognosis is generally favorable. In sorofulous or tubercular cases, however, or in those whose blood has become altered by some zymotic disease, the suppuration is apt to pass into the chronic stage, with large perforation of the drum and great impairment of hearing. But in cases of fair general health that are promptly treated, the discharge generally ceases in several weeks, the membrana tympani heals, and the hearing is restored. Sometimes the suppurative process perforates the cranium and extends into the brain, resulting in the death of the patient. There may be, however, from severe inflammation in this locality, marked cerebral symptoms without actual involvement of the brain or meninges. A few years ago a case under my care illustrated this. The patient was a child eighteen months old, who had a suppuration of the middle ear, of several months' standing. He developed marked cerebral symptoms and died. A post-mortem made by Drs. George Strawbridge, J. H. Packard, L. B. Hall, and myself, showed no evidence of inflammation within the cranium, except a few drops of pus beneath the periosteum. There was no perforation of the cranium. The symptoms appear to have been due to the close proximity of the inflammation to the brain, and death was attributed to exhaustion. In some cases pus becomes imprisoned in the mastoid cells, and being retained there, may cause pyæmia and even death. I believe that death is often attributed to other causes, when a thorough and careful examination would show it to have been due to disease in the middle ear.

The treatment must vary with the stage of the disease and the nature of the pathological condition. If the case is seen early, within a few hours of the appearance of pain, or when there is, as yet, simple hyperæmia, the attack may often be cut short by local bleeding, with a saline cathartic, and rest in bed. This is well illustrated by the following case: J. D., aged 35, carpenter, in good general health, was seized with intense pain in the left ear about five o'clock in the morning. He came under observation at eleven o'clock, six hours after the beginning of the attack. The pain was then so intense that he walked the floor and begged that something might be done to give him relief. The pain was aggravated by pressure over the tragus. There was some fever. On examination the drum was found to be greatly injected. Three foreign leeches were immediately applied in front of the tragus, and he was directed to go to bed. A dose of sulphate of magnesia was also given. The result of the treatment was highly satisfactory. He returned the next morning without any pain whatever; the injection of the drum was much less intense, and he expressed himself as feeling entirely well. He remained under observation for about a week, at the end of which time nothing abnormal could be detected about his ear. This case, I think, would undoubtedly have gone on to suppuration but for this prompt and decided treatment.

It is not often, however, that a case comes under observation at so early a period. Generally pus has formed, and often the discharge has commenced when treatment is applied for. If pus is detected by the bulging of the drum, it is better to perform paracentesis than to wait for a perforation to take place, as relief can thus be afforded sooner, and the cut made with a knife will heal more readily than the irregular opening made by the pus. With a good forehead mirror and speculum, to bring into view the drum, the operation is not difficult of performance. Pain is best relieved by hot fomentations. Flannel cloths, wrung out of water as hot as can be borne, and laid over the ear, answer best for this purpose. They should be changed every few minutes, and hot water should be added from time to time. This should be kept up from ten to twenty minutes at a time, and repeated every hour or two. During the intervals the ear should be well protected by a large pad of cotton, or by flannel cloths tied over it. Sometimes hot water, poured into the external meatus, will give relief. Of course this must be done cautiously. Among other domestic remedies, the core of a roasted onion, tied over the meatus, is worthy of trial. A hop pillow is also of decided value. It should be heated and some whisky sprinkled upon it, when it may be applied to the affected ear. When the pain is very great and there is much injection of the drum, leeches often give prompt and decided relief. From one to three (foreign) may be applied in front of the tragus or over the mastoid, according to the seat of greatest pain. A blister often acts equally well. The cantharidal collodion is best adapted for this purpose. It raises a blister in from four to eight hours, and seldom fails to give great relief. Throughout the entire course of the treatment cleansing is of the greatest importance. During the acute stage, the syringe, if used at all, must be used very gently, as a stream of water thrown forcibly against the drum would greatly aggravate the pain. The cavity of the middle ear may be cleared of pus by gentle inflation with Politzer's bag, or by the Valsalvian method, and the external canal may be cleansed with absorbent cotton, by means of a cotton holder, with very little discomfort to the patient, if proper care be exercised. Stimulating applications should not be used during the acute stage; indeed, they should not be used until the parts have become pale and flabby in appearance. Sulphate or acetate of zinc, of the strength of 1 to 5 grs. to the ounce of water, or nitrate of silver, 1 to 3 grs. to the ounce, may then be applied with benefit. Powdered boracic

acid, blown into the external canal in small quantities, with an insufflator, such as is used for making applications to the pharynx, has given me more satisfaction than anything else I have used. Indeed, we use it almost exclusively at the present time in the Philadelphia Dispensary. It possesses the additional advantage over most other applications, of being a disinfectant. Perhaps its efficacy depends mainly on this fact. Certain it is, that under its use a larger proportion of our patients get well than under any other treatment we have ever used. Iodoform is another remedy of great value. It is particularly adapted to cases where there is a tenacious muco-purulent discharge. It is unfortunate that its odor is so objectionable to many people, as it is difficult to get patients to use it for any length of time. I have recently had a case of three years' standing, which, after five months' treatment with nitrate of silver and boracic acid, was little, if at all, improved, that is now, after one month's treatment with iodoform, nearly well. It may be applied on slightly moistened absorbent cotton, by means of a cotton holder.

Abscesses over the mastoid are not uncommon. These should be opened as soon as pus has formed. The opening should be free and extend down to the bone. Poultices should afterward be applied and the incision kept open by the introduction of a tent until the swelling has disappeared and pus ceased to form. If pus has become imprisoned in the mastoid cells trephining is the proper and necessary thing to do. The great difficulty consists in making a positive diagnosis. Of the large number of cases treated at the Philadelphia Dispensary, we have had during the past five years but two deaths. In the one above referred to, the post-mortem demonstrated clearly that trephining could not have saved the life of the patient. In the other case, that died during the present week, although no post-mortem could be held we have no reason to feel that the operation could have saved the life of the patient. I think our experience shows that the operation is very rarely necessary.

To allay the unpleasant odor of aural discharges, syringing the ears with a weak solution of permanganate of potash answers very well. The boracic acid treatment above recommended prevents, if the applications are made sufficiently often, the offensive odor almost entirely. Frequent cleansing, however, is necessary, whatever other remedies are used. As there is in most cases throat complication, this should be treated in connection with the ear. Nasal catarrh should also receive appropriate treatment.

As regards general treatment, tonics and alteratives are required in most cases. Morphia is often necessary in acute cases, to allay the pain. The bowels should be kept open.

Occasionally there are cases in which, whenever the discharge ceases there is great pain, with fever, and sometimes apparently grave cerebral disturbance. In such cases it is not generally wise to attempt to arrest the discharge, and, should it stop, it is well to endeavor to re-establish it by poultices and other hot applications. By persistent cleansing and attention to the general health, such patients can sometimes be cured; but they are usually unpromising cases.

While in most cases the treatment above outlined will arrest the discharge and heal the suppuration, it is not wise to promise, in chronic cases, any improvement in hearing. Indeed, some cases do not hear as well after the discharge has ceased as before. In recent cases, however, the hearing generally comes back to nearly or quite the normal degree of acuteness. In cases where the suppuration has healed, but a perforation of the drum remains, it is well to protect the ears with a little cotton in the meatus during very cold weather, as the cold air in the middle ear may set up a new inflammation, and necessitate a repetition of the same treatment. This, briefly and imperfectly presented, is the treatment that I have found most efficacious in this troublesome class of cases.

REMARKS UPON THE PAPER.

In referring to treatment, Dr. H. C. Paist mentioned the successful plan of maintaining continued counter-irritation over the mastoid region, by means of creasote. This has afforded very satisfactory results.

Dr. Henry Bèates desired to direct attention particularly to the fact that the majority of instances of suppuration of the tympanum occurred during or about the period of increased development of the teeth in infancy, again, about the time of eruption of the six-year-old molar, and lastly, at the appearance of the "wisdom tooth." A very important factor in the maintenance of suppuration of the tympanum, too frequently overlooked, is the existence of carious teeth. The six-year-old molar erupts in an imperfectly developed condition, frequently deficient in enamel, which accounts for the almost constant state of caries of this particular tooth. The continuity of structure of the elements of the oral cavity and ear must not be lost sight of. In pre-natal life a structure, Meckel's cartilage, exists which is in direct continuation with the handle of the malleus, indeed, may be considered a part of that ossicle, and it is not unreasonable to infer that a strong sympathy of physiological action exists throughout life, by reason of identity of structure, notwithstanding that the cartilage early shrivels and severs its connection with the malleus. The innervation of the tympanum is identical with that of the oral cavity, in the main. The facial and auditory nerves in the internal auditory meatus communicate by two or more filaments, and the facial, by means of the vidian nerve, connects directly with the sphenopalatine ganglion. The chorda-tympani nerve serves as a bond of union with the lingual, and the petrosal minor with the otic ganglion. These ganglia being in close communication with the carotid plexus of the sympathetic, complete a circuit by which the cavities under consideration are virtually and physiologically one. The enamel organ and dental follicle develop from the same structure which contributes to the formation of mucous membrane that covers all these regions; also the chorda-tympani nerve. The importance of this anatomico-physiological condition is manifest, and indicates the necessity of correcting any coexisting disease, as carious teeth, naso-pharyngeal catarrh, or eruption of teeth, in order to secure a perfect cure, in sup-

puration of the tympanum. I have in several instances seen long standing suppurations get well, with no other treatment than cleanliness, after dental trouble has been remedied by a competent dentist.

Dr. Joseph Gibb presented a specimen of pulmonary anthracosis obtained from a male adult, who died from chronic Bright's disease. During life no evidences of pulmonary trouble were present. There were manifestations of incipient inflammatory disintegration at apex of one lung, discovered post-mortem. The deposit of coal dust was very marked, completely discoloring and disguising the pulmonary structure in areas.

Dr. Henry Rihl reported a case of immense scrotal hernia, which had existed for years. A truss had never been worn, the only support having been a suspensory. The history obtained from man and wife, and the professional opinions that had been given, led to the opinion that it was irreducible. Symptoms of strangulation, however, occurring, the doctor was called, and after producing complete anæsthesia with ether, a portion only of the protruding intestine was returned. Being unable to reduce the remainder he regarded it an instance of partially irreducible hernia, and left the patient. On calling the following day he was surprised to find that the whole mass had disappeared and the hernia was completely reduced. The character or nature of this hernia is a question to be answered. Was it a partially irreducible hernia, with slight adhesions, which were severed by the attempts at taxis? Dr. Montgomery replied that he did not consider it impossible to have been as the Doctor mentioned. Dr. Montgomery narrated instances of femoral hernia in females under his care, and especially one, that had been regarded by several physicians as irreducible. The protrusion was very large, almost that of an adult cranium. Anæsthesia and properly applied taxis resulted in reduction. In taxis it is essential to manipulate in such a manner that the soft or fluctuating mass is not forced over the ring as a cushion, a method frequently seen and as frequently unsuccessful. The mass must be moulded, as it were, wedge-shaped, when properly directed force will effect reduction. He mentioned a case where, in operation, the hernia was partially reduced, a small portion of intestine remaining constricted. Peritonitis developed, evidently, however, not from the constriction, resulting fatally. The constriction was detected post-mortem. In another case the hernia was composed almost totally of omentum. The small portion of intestine was greatly discolored. Omentum was removed and the suspicious intestine returned. Peritonitis and death resulted. Should another instance occur with intestine so gangrenous he would enlarge incision to abdominal cavity and excise the disintegrated intestine.

The doctor also narrated the following very interesting history: A professional gentleman from a distant State began to suffer, late in life, from attacks of severe megrim. The neuralgic headaches began to occur with greater frequency and severity. Neuralgic pains eventually developed, lasting several days, which were independent of the cephalalgia. After the existence of this trouble for nearly two years, paroxysms of vertigo and an inclination to fall toward the right occurred. During the cephalalgia the patient seemed auto-unconscious, and sat in an apparent stupor, but if an individual would enter his apartment, questions propounded were answered rationally. After the stupor passed off, which it did in from two to four days, the patient had no recollection of being interrogated, much less of replying. These paroxysms became more severe, frequent and prolonged, culminating in epileptoid spasms. This condition lasted four years. The physicians pronounced it fatty degeneration of heart, from the fact that the cardiac murmur and impulse at times were distant, very feeble, and at times irregular. Cerebral neoplasm was also diagnosticated, and even malaria. Inquiry elicited the fact that thirty years previously a chancre had been contracted, *but not followed by constitutional phenomena.* During the thirty years his habits were strictly temperate, with the exception of the use of tobacco, and his health remarkably good. The diagnosis was syphilitic affection of cerebral meninges, and the treatment adopted in accordance. The results are everything to be desired. Health is now excellent and the patient, apparently none the worse for his years of suffering, is engaged in the practice of his profession.

A New Test for Albumen in Urine.

Dr. Wm. Roberts thus writes, in the *Lancet:* When an albuminous urine is treated with a saturated solution of common salt, not the slightest reaction takes place; but if the brine be slightly acidulated with hydrochloric acid, the albumen is thrown down as a dense white cloud. This reaction constitutes a most delicate test for albumen in the urine. The best degree of acidulation for this purpose is obtained with about 5 per cent. of the dilute hydrochloric acid of the Pharmacopœia. A little more or a little less acid makes no appreciable difference in the sensitiveness of the test. Common salt dissolves in about two and a half times its weight of water at 60° F., and increase of temperature does not sensibly increase its solubility. The salt of commerce is always more or less dirty, and the solution requires filtration to fit it for use as a test. The salt solution should be fully saturated, otherwise the observer is apt to be led into error. In preparing the test with our common English measures the readiest plan is to mix a fluid ounce of dilute hydrochloric acid with a pint of water, and to saturate this with common salt, and filter. Dilute hydrochloric acid may be replaced by dilute sulphuric, dilute nitric, or dilute

phosphoric acid. All these acids are of the same saturating strength in the British Pharmacopœia, and all of them yield, with saturated salt solution, an equally sensitive reagent for albumen. Even acetic acid may be used, but the delicacy of the test in that case is not quite so great as when it is prepared with one of the mineral acids. The method of applying the brine test is similar to that followed with nitric acid. A portion of the suspected urine is placed in a test-tube, the test-tube is then held very much aslant, and the salt solution is allowed to trickle along the sides of the tube to the bottom, so that it may form a distinct layer below the urine. If albumen be present, a white, cloudy zone appears at the junction of the two fluids. Or the proceeding may be reversed. The salt solution may be first introduced into the test-tube, and then the urine added, with the same precautions as before, so as to obtain two distinct layers, one above the other, in the test-tube. It is important to be aware that the precipitation of albumen by acidulated brine is not due to a true coagulation. In this respect the brine test differs from nitric acid and boiling. In the two latter cases the albumen is transformed into the insoluble modification, which is known as "coagulated albumen." But when albumen is thrown down from urine by acidulated brine, the precipitate is not insoluble; on the contrary, it is redissolved by free addition of water, or even by free addition of the albuminous urine itself. It is therefore essential to the efficient application of the test that the salt solution should be in excess at the point of expected reaction. This end is obviously secured in the above-described methods of testing. It may also be secured by adding to the suspected urine a volume of the salt solution at least equal to that of the urine in the test tube. If this point be not attended to the test is unreliable. For instance, if acidulated brine be added, drop by drop, to an albuminous urine, and the mixture shaken up after each addition, the first few drops either occasion no turbidity whatsoever or the turbidity produced disappears on shaking. But when by successive additions the quantity of brine approaches to or surpasses the volume of urine operated on, the turbidity remains permanent. In point of delicacy the salt test stands on a par with nitric acid. The minutest trace of albumen detectable in the urine by nitric acid is also detectable with equal ease by acidulated brine. In high-colored urines the brine test is distinctly superior. In this class of urines nitric acid produces a deepening of the tint, with, often, a disengagement of gas, which interferes with the sensitiveness of the reaction, but the brine test neither alters the tint nor causes disengagement of gas. On the other hand, I think that nitric acid gives a better idea of the quantity of albumen present by the density of the white cloud produced, than does the brine test. In addition to albumen, acidulated brine precipitates peptones, which are sometimes present in urine; so that occasionally a slight cloudiness is produced by the salt solution where nitric acid and boiling (which do not precipitate peptones) produce no reaction. This distinction in the action of the brine test may hereafter lead to interesting information. In dense urines, highly charged with urates (but not containing albumen), the addition of nitric acid sometimes throws down the amorphous urates in the form of thick white clouds, and it is necessary to apply heat to distinguish with certainty the cloudiness so produced from cloudiness due to albumen. The salt test does not throw down the urates in this way. It is well known that the urines of patients who are taking large doses of resinous substances (such as the resin of copaiba), although free from albumen, yield a cloudiness with nitric acid in the cold, but if the urine be previously made hot, nitric acid produces no such reaction. This difference serves to distinguish cloudiness due to resin from cloudiness due to albumen. The brine test also produces a cloudiness in resinous urines, and the reaction occurs whether the urine be hot or cold. To avoid the fallacy thereby arising, all that is necessary is to add an excess of the urine which is being tested. If the cloudiness be due to albumen it disappears on such addition, but if it be due to resin, the cloudiness does not disappear on the addition of more urine. One of the chief advantages of the salt test is its incorrosive character. It does not stain nor burn holes in garments and carpets, nor fleck the hands with yellow spots. The use of it makes it possible to arrange a pocket-case for urine testing that shall not be a terror to the wearer. From this point of view the substitution of the salt solution for nitric acid will be a real boon to practitioners.* The salt test has this additional convenience, that it enables us to test successively for albumen and sugar on one and the same sample of urine. The suspected urine is first tested for albumen with the salt solution, and then Fehling's solution, or, still better, a pellet of the solid Fehling's test sent out by Cooper, is added, and heat applied. After boiling a few seconds the absence or presence of sugar is ascertained. The admixture of the brine in no way interferes with the copper reaction, in case sugar should exist in the urine.

* I have carried about with me for some months past a little pocket-case (which is only a stiff-backed cigar-case) which I have found a useful and safe clinical companion. It contains a book of litmus papers; a narrow corked phial filled with acidulated brine; a test tube charged with Coop r's pellets of the solid Fehling's test, guarded with an india-rubber stopper; and, lastly, an empty test-tube, also provided with a cork. This compact arrangement furnishes the means of ascertaining the reaction of the urine, and of testing it in the most delicate manner for albumen and sugar. The empty test-tube also serves to carry home a specimen of the urine for further and more minute examination. The "pellets" (made after a suggestion of Dr. Pavy) are sent out by W. T. Cooper, chemist, 26 Oxford street, London.

Interstitial Fœtation.

The following rare and instructive case has been recorded in the *British Medical Journal*, by Dr. Carr Holstok Roberts:—

On Sunday evening, October 1st, at 10.30, I was requested by the husband of one of my patients to come and see her, at once. He stated that they had gone to bed as usual, and had been asleep, when his wife awoke him, and said that she been waked by "pains in the stomach, and couldn't get rid of them, nor go to sleep again."

He had given her some brandy, but without any good effect.

I found her in bed, a tall, stout woman, aged 32, complaining of pain in the abdomen, which was neither swollen nor tender on pressure. She was also suffering from sickness and slight diarrhœa, which she attributed to her having taken some strong pills. The vomit appeared to be semi-digested food, and the motions were such as would be produced by a purgative. The patient's skin was cool and moist, her pulse good, and her respiration and temperature both normal. She was perfectly conscious, calm, and collected, and there was nothing whatever to indicate such a sudden and fatal termination as took place. She informed me, on inquiry, that she had missed two periods. Her general health had always been good. Her two only children had both been born at the full period, and are both living. The younger, fourteen months old, had been weaned about two months. She had never had a miscarriage; but, thinking it most probable that such was the nature of this illness, I gave her opium, ammonia, and chloric ether, and ordered hot fomentations and linseed poultices to the abdomen, with a little brandy at intervals, leaving instructions that I was to be sent for, if necessary. I was not, however, called again until 8 A. M. the following morning, when she had suddenly become much worse. I then found her in a state of collapse, and evidently dying, but perfectly conscious, and complaining of a great desire to pass water. She had, however, done so during the night, and the bowels had been once relieved; the vomiting had not recurred. I passed a catheter, and found that the bladder was empty. She became rapidly worse, but remained perfectly conscious until 10.30, when she expired.

Necropsy.—There were no external marks of violence; the body was very fat, considering her age; the abdominal cavity was filled with very nearly six pounds of clot, and five pints of a bloody fluid. Floating in the fluid was a fœtus, at about the second month of development, enveloped in its membranes, and with the placenta attached. At the upper part of the uterus there was a rupture, close by the right Fallopian tube, large enough to contain three fingers, and looking like a sac, the walls of which were extremely thin. The true cavity of the uterus, which was laid open and examined by Mr. Doran, contained a decidua, as is often seen in cases of tubal gestation. There was no communication between it and the interior of the uterus, which weighed exactly eight ounces. The heart was fatty and somewhat flabby, and was perfectly empty, as were also all the large blood vessels. The other organs of the body appeared perfectly healthy. The head was not examined. The entire internal organs have been sent to the Museum of the Royal College of Surgeons, where no specimen of interstitial gestation was hitherto to be found, though there is a fine series illustrating tubal pregnancy. I have no remarks to make on the case, except as to the absence of the graver symptoms until within so short a time of the death. The blood had evidently continued oozing out, until there was no more to come. The apparent desire to pass water was evidently caused by the pressure of the clots, etc.

Pulmonic Surgery.

The *British Medical Journal* says that Dr. Koch, of Dorpat, communicates (*Deutsche Med. Wochenschr.*, 1882, No. 32) the results of two cases in Leyden's clinic, in which he had operated for chronic putrid bronchitis, with bronchiectasis. The first case was that of a man, aged 24, with the physical signs of contraction of the right lung, cavities in the right base, and catarrh of the right apex. The sputum indicated gangrene of the lung, and was unaffected by treatment. On June 26th part of the right sixth rib was resected, and after it had been ascertained that the two layers of pleura were completely united, the thermo-cautery was gradually pushed through the lung to the mediastinum. It opened a cavity of the size of a child's fist, about three fingers' breadth from the surface of the lung. The sputum expectorated sank at once from 400 to 120 cubic centimetres daily. On June 30th, part of the eighth rib was resected and the thermo-cautery passed through the base of the lung, without, however, entering any considerable cavity. Exploratory puncture with a syringe showed a purulent collection in front of the vertebræ, and on July 11th this was laid open, between the eighth and ninth ribs, below and internal to the angle of the scapula. The condition of the patient at the date of publication (August 5th) was most satisfactory, although the expectoration had not quite ceased; and it was proposed to explore still further the base of the lung.

The second case was that of a woman aged 29, brought into hospital with jaundice, and a putrid expectoration amounting daily to between 800 and 1000 cubic centimetres. After a preliminary aspiration of the right thoracic cavity on July 15th, four inches of the sixth rib was resected; and, a hollow needle having been passed through the anterior axillary line, in the direction of the right auricle of the heart, the thermo-cautery was pushed in the same direction. Two inches from the surface of the lung it entered a cavity, about the size of the closed fist; and, on pushing it upward and backward from this cavity, as guided by exploratory puncture, it entered another cavity, of the size of a child's head, and containing one thousand cubic centimetres of putrid fluid. The cavities were washed out with thymol solution, and three thick drainage-tubes inserted. The patient collapsed after the operation, but remained alive for a week, during which time the expectoration was completely absent, and *post-mortem* the surfaces were found covered with healthy granulations. The cause of death was less the operation than a phlegmonous inflammation of the portal vein, a lobular broncho-pneumonia of the base of the left lung, from the presence of a foreign body, and a chronic septicæmia, which had existed for some time. The writer promises a further communication on the subject, in conjunction with Dr. Hiller, who is at present making extensive observations in Leyden's clinic. Meanwhile, he considers that operative interference is indicated in cases of single cavities, especially if near the surface, in cases of acute gangrene, and also in cases of foreign bodies not removable by the trachea, in putrid bron-

chitis, and in the rare cases of localized tuberculosis of the lung.

Disinfection by Heat.

The Medical Times and Gazette says:—

The superiority of heat over all fumigations and other reputed disinfectants is now generally recognized, and local sanitary authorities have already in many districts set up disinfecting ovens or chambers, of one or other kind. It is, however, of the utmost practical importance that the intensity and duration of the temperature required for the destruction of bacilli and of spores should be fully appreciated and attended to, if such "disinfection" is to be really effective, and not a dangerous delusion. Drs. R. Koch and Wolffhügel, after a long course of carefully conducted experiments, find that bacteria are not killed until after an exposure of one hour and a half to a temperature of 100° C. (212° F.). Spores of fungi require a greater heat, viz., 110° to 150° C. (230° to 300° F.), for at least as long, while nothing less than a temperature of 140° C. (285° F.), continued for three hours, suffices to kill the spores of bacilli, as those of anthrax. These are the germs with which we have to deal in practical disinfection. Such a temperature will, in three hours, infallibly kill these spores, but since it takes that time to penetrate to the centre of even small bundles of clothes or of pillows, a further exposure of like duration will be required for their complete disinfection, and few articles of clothing or bedding will bear such treatment without serious damage. It is to be regretted that Drs. Koch and Wolffhügel did not repeat their experiments with moist air, for there seems to be no reason to fear that the presence of a proportion of vapor not amounting to saturation can detract from, if indeed it do not actually enhance, the efficacy of the heat; while it is known that the most delicate fabrics, as ostrich feathers, dyed silks, etc., are uninjured by a temperature of 300° Fahr. under these conditions, and if the moist air be forced in under pressure, as in W. Lyon's apparatus, the penetration of the heat is greatly facilitated. The general conclusion to be drawn from these experiments, which are described in detail in the *Mittheilungen des k. Gesundheitsamte*, Bd. 1, seems to be that nothing less than a three hours' exposure to a temperature of little short of 300° Fahr., with precautions to insure the penetration of every part of the articles subjected to it, is sufficient. How this is to be attained is a question of detail, but at present it certainly appears that preference is to be given to the particular apparatus above named.

Employment of Prolonged Baths in Therapeutics.

In a recent editorial in the *Progrès Médical*, M. Leloir recommends the establishment in the Paris hospitals of apparatus for prolonged or continuous bathing, similar to those he has lately observed in Kaposi's service at the general hospital at Vienna. This consists of a mechanical bed plunged in a large wooden reservoir lined with zinc; water is continuously introduced at a proper temperature, and the patient eats and sleeps in his bath. M. Leloir observed patients who had remained continuously 50 or 100 days in the bath without leaving it, and who were by no means fatigued after their prolonged sojourn in the water; they spoke highly of the relief they obtained from their sufferings.

This system of bathing is not only very efficacious, as has long been known, in grave cutaneous affections, rebellious to all other forms of treatment (extensive inflamed psoriasis, pemphigus, etc.), modifying the morbid condition of the skin, calming irritation, and lowering the temperature; it has also recently proved of very great service in other than cutaneous affections.

The physicians in the Vienna hospitals have obtained very excellent results in the treatment of extensive burns and of localized gangrenous sores. Under the influence of a continuous sojourn in the bath the pain of extensive burns disappears, fever falls, the patients can rest, and cicatrization takes place with great rapidity.

But it is particularly in the treatment of gangrenous sores, such as the enormous ulcers left after prolonged decubitus in typhoid fever, hemiplegia, etc., that the results are most remarkable.

After 15 days the largest eschars become detached, the ulcer spreads no further, and soon presents a red, healthy surface, which cicatrizes with great rapidity. M. Leloir observed a case where the sacrum was denuded and the soft parts about it deeply ulcerated, enter in course of cicatrization twenty days after the commencement of treatment. Finally, no symptoms of hectic fever or of septicæmia are observed. These excellent results are explained by the influence of the prolonged bath itself, and also by the complete absence of pressure over the ulcerated parts, on account of the diminution of the weight of the body in the water.

Quinine and its Salts.

The following résumé in a recent number of the *Progrès Méd.*, of the physiological effects and therapeutic uses of the quinine salts may prove useful.

Principal Physiological Effects.—Quinine is an antiseptic, induces siallorrhœa by reflex action (bitterness), diminution of tactile sensibility; of acuteness of hearing, buzzing in the ears, hallucinations of hearing, vertigo, confusion of ideas, exaggerated beating of carotids, cephalalgia (quinic intoxication), titubation, apathy, general prostration, slight dilatation of pupils, nausea. After larger doses, vomiting, delirium, surdity, sometimes cecity or aphasia may ensue. Toxic doses may induce collapse, convulsions and death.

The other physiological effects are, augmentation in volume of the red globules (resulting from a greater quantity of oxygen), disappearance of the amœboid movements of the white globules, diminution in volume of the spleen.

In small doses (under a gram), acceleration of the cardiac contractions, then slowing-up and fall of blood pressure; finally, arrest of respiration followed by cardiac paralysis. The action on the temperature is insignificant in the healthy individual, and outside of the febrile conditions connected with malaria its action as an antipyretic is subject to much controversy.

The elimination is rapid, principally by the urine, which becomes more abundant; there is almost complete suppression of transpiration.

In rare cases a scarlatiniform eruption and hæmaturia have been observed after the administration of quinine.

The salts of quinine have latterly been employed hypodermically in Europe, but often produce local accidents, pains, persistent indurations, and often abscess. The chlorhydrate has proven the best salt for hypodermic use.

Use in Therapeutics.—In remittent or intermittent fever of malarial origin, neuralgia, intermittent fever, febrile manifestations symptomatic of hepatic abscess, empyema, etc., leucocythemia, insomnia, hay fever, albuminuria (Devonves), whooping-cough, septicæmia, gout, scrofulous keratitis, phlyctenular and pustular conjunctivitis, typhoid fever, acute articular rheumatism, etc., the drug can be administered hypodermically in urgent cases.

The Temperature in the Early Stage of Phthisis.

The *Medical Times and Gazette* says:—

The treatment of phthisis is really efficacious only at its early stage, and it is then that the lesions do not furnish very evident physical signs, and consist chiefly in delicate modifications of the *timbre* of respiration, perceptible only to the practiced ear. Prof. Peter is of opinion that at this early period great aid is obtained in diagnosis by examining the local temperature of the thorax opposite the apex of the lung. The local temperature in early phthisis increases by nearly a degree; while in chlorosis, which is often confounded with phthisis, the temperature in this locality is below the mean. In the case of a young girl, upon which he recently lectured, there were present irregular menstruation, pallor, dyspepsia, palpitations, vertigo, etc.; and on a minute auscultation being made, there was also observed toward the apex of the lung some prolongation of expiration, and some of the roughness (*rudesse*) of inspiration, upon which Dr. Grancher lays great stress. The axillary temperature was 37.3° Cent., while that taken in the second intercostal space, where the prolongation of the expiratory sound was heard, was 36.8°, exceeding the normal of this locality, which is 35.8°, by a degree. In another girl presenting quite similar symptoms, but in whom the respiration was quite normal, the axillary temperature was 37.7°, while that of the thorax was below the normal, viz., 35.6°. In a third girl, with similar symptoms, the axillary temperature was 37.4°, and that of the thorax only 35.4°. To be conclusive, these cases would require further observation; but the coincidence of the indications furnished by auscultation and the thermometrical exploration seem to be of sufficient interest to be noted.

—At a recent meeting of the Board of Trustees of Jefferson Medical College, Doctors Joseph Hearn and Oscar H. Allis were elected members of the surgical staff of the hospital, to fill the vacancies caused by the resignations of Professors John H. Brinton and Samuel W. Gross.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The "Visiting List, or Physician's Diary for 1883," issued by William Wood & Co., New York city, has appeared, and is a well made and convenient pocket manual of the kind.

——The new drugs introduced of recent years are reviewed by Mr. B. F. Kilmer, in a report to the New Jersey Pharmaceutical Association, reprinted in pamphlet form. It is a carefully prepared paper.

——The diagnosis of brain tumors is often very obscure, and the paper by Dr. C. K. Mills, on that subject, reprinted from the *Archives of Medicine*, is timely and instructive. He cites the notes of twelve cases.

——Godey's Lady's Book for December appears with an unusually rich and attractive array of pretty illustrations, stories, and instructive matter for the ladies. All the recent fashions are depicted, and a great number of valuable hints for housekeeping and how to make home attractive, are added.

——The folly of Mr. Bergh's opposition to vaccination is well set forth in the reprint of a paper by Dr. C. M. Martin, of Greenville, Mich. It is a public misfortune for a man in many respects of sound intellect, like Mr. Bergh, to deal dogmatically with subjects about which his information is so scanty, and his logic so loose.

——In a duodecimo of 48 pages, by Dr. G. L. Austin (Lee & Shepard, Boston; cloth, 50 cts.), the author presents to non-professional people some easy methods of analyzing water, to the extent of deciding whether it is wholesome or noxious. His methods can be recommended as safe and reasonably accurate.

——The "Ephemeris of Materia Medica," published from time to time by the Squibbs, of Brooklyn, the sixth number of which is now before us, is an honest, scientific, well edited casual visitor. The last number has much to say about the oleates, and in passing gives our friend Dr. Shoemaker one or two raps. It is a subject well worth further investigation, both chemical and clinical.

——The Report of the Conjoint Session of the North Carolina Board of Health and Medical Society of North Carolina, held last May, makes

a pamphlet of 66 pages. It contains an essay on Preventive Medicine, by Dr. W. P. Beall, and the proceedings of the meeting. The Report of the Secretary contains some valuable suggestions on the prevention of river fever, a form of malarial disease common in that State.

——In a little pamphlet on the mechanical therapeutics of uterine diseases, Dr. James Guild, Jr., of Tuskaloosa, Ala., makes the very correct assertion—

"With a correct understanding of the normal anatomy of the pelvic organs, and a thorough appreciation of uterine pathology, and then to omit mechanical support as a remedial agent, appears to me incomprehensible. Certainly, if the mechanism of its action is understood, such a course is more the result of prejudice than of the inefficiency of such support itself."

He gives the particulars of a number of cases in support of his views.

——"Lippincott's Magazine" for December opens with a finely illustrated article on Block Island, by Charles Burr Todd. "Newburgh and its Centennial" is the title of a valuable historical paper, recounting the final events in the War of Independence. "The Earlier and Later Work of Mr. Howells" is written with discernment. "The Career of Felix Mendelssohn" is ably outlined by Edwin D. Mead. "A Day in Coyoteville," by Laura Wells Morse, gives an amusing sketch of western life and manners. Among the short articles in the "Monthly Gossip" is one by Amelia E. Barr, describing the childhood and early home of Adelaide Neilson.

——The etiology of consumption is the subject of a paper read before the Ohio State Medical Society, and appearing as a reprint, by Dr. D. N. Kinsman, of Columbus, Ohio. His views are tersely summed up in the following paragraph:—

"Thus have I endeavored to present the pathological features of these two forms of lung disease so often confounded. They have no features in common. From all I have learned concerning tubercle I believe it is the product of a specific inflammation. If the disease is specific there can be but one efficient cause, and we must abandon the theory that tuberculosis can have multiple efficient causes. Attendant circumstances may hasten or retard the development of tuberculosis but to conclude that they can do more, is illogical. Tubercle is inoculable and contagious. Tuberculosis does not, therefore, arise de-novo, but depends upon a germ, introduced from without."

He shows, moreover, that this distinction has often been maintained by practical clinicians.

BOOK NOTICES.

The Pharmacopœia of the United States of America. Sixth Decennial Revision. New York: Wm. Wood & Co., 1882. Cloth, 8vo, pp. 488.

This long expected and carefully revised work will be welcomed by the pharmaceutists of our country with great interest. In addition to the Pharmacopœia proper, it contains an historical introduction, notices on percolation, temperature, weights and measures, a list of reagents, tables of elementary substances, thermometric equivalents, specific gravity, solubility, saturation, etc., and separate tests of articles added and dismissed from the Pharmacopœia. The index is very complete, and the committee have throughout paid conscientious attention to distinctness of statement and accuracy in proof reading.

The lists of articles added and dismissed from the Pharmacopœia are often calculated to surprise one, in reading them over. So many are dropped which were once famous as remedies and still hold their own in the opinion of a respectable minority, so many are introduced with whose remedial properties the profession is but slightly acquainted! We know, however, that this selection and rejection were both the result of long and open discussion.

A Treatise on Therapeutics, Comprising Materia Medica and Toxicology; with Especial Reference to the Application of the Physiological Action of Drugs to Clinical Medicine. By H. C. Wood, Jr., M.D. Fourth edition, revised and enlarged. Philadelphia: J. B. Lippincott & Co., 1882. One vol., 8vo, pp. 736. Price, cloth, $6.00.

There is no better work than this for the study of the medical properties of drugs as based upon their physiological action. The present edition introduces all the results of the experiments in this direction which have been reported either in this country or Europe. The industry of the author is manifest on every page, and those who give their adhesion to his general theory of the method of investigating remedial agents by noting their action on the human body and the lower animals in a state of health, will find in his pages a thorough synopsis of what has been done in this branch up to the present.

The work is clearly printed, and has several excellent indexes, which add much to the convenience of using it.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D.,
JOSEPH F. EDWARDS, M.D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

After Jan. 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, will be commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, $2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for strictly in advance and directly to this office.

THE SCIENTIFIC POSITION OF MEDICINE.

It is a constant surprise to the physician to discover the opinions about doctors and medicines and remedial theories which prevail among the public. We do not now speak of the ignorant masses who have had no training in the exact sciences, and may be said not to know how to think on any subject, but of reasonably well educated men and women.

This ignorance shows itself in a variety of ways. It is at the foundation of the success of the out-and-out charlatan, who trades upon it with effrontery, and considers it the chief element of his stock-in-trade. Though often extremely and palpably ignorant, not able to write a sentence correctly, yet his brazen assertions are taken as truth, and he is paid to exercise a knowledge which all know can only be obtained by years of arduous study.

Reckless hypotheses are dignified by the name of "systems" or "schools," and are asserted, by people of excellent general intelligence, to be reasonable and scientific. One such "school" will use nothing in the shape of a remedy but vegetable productions; another discards every drug or article of food derived from the animal kingdom; a third will reduce its doses to a quantity so small that they become even mathematically unappreciable. Yet all these "systems" find honest adherents and defenders.

The number of believers in miraculous cures, in restoration to health by prayer, or vows, or pilgrimages, or amulets, is by no means small. Doubtless these methods are at times efficacious through indirect agencies. But it is a sad commentary, both on the religion and the science of the age, that such occurrences are heralded and accepted as direct results, in what are called intelligent circles.

There is, in fact, a disposition to look on really scientific physicians with distrust. They are accused of jealousy when they endeavor to point out the logical inconsistency of the pseudo-scientists of the day; they are charged with an effort to conceal knowledge when they frankly state the difficulties in laying a medical question before a non-medical audience; their knowledge

is belittled or denied because it is impossible to give it a concrete and uniformly applicable formula.

The legitimate and natural differences of opinion on medical points, arising from the inherent complexity of the problems and the infinite variations of cases, are used to make it appear that both the methods and the results of medicine are worthless.

All these popular errors arise from a deficient mental training, and a lack of comprehension of the nature and limitations of medical studies. We may expect them to disappear as general education is raised. An appreciation of the logical methods used in medicine will grow gradually, and the knavery and absurdity which have long clung to practice will be shaken off as parasites.

Clear views in the profession itself will greatly aid to this end. Skepticism or credulity is each often carried too far by physicians. The fortunate medium between routinism and novelty-seeking must be sedulously sought for, and a proper appreciation of the true position of medicine in the category of the sciences must be impressed early on students.

RIVER POLLUTION AND THE DISPOSITION OF SEWAGE.

The *Westminster Review*, in a recent issue, contains a valuable and practical article on this very important subject, from the pen of Mr. URQUHART A. FORBES.

It is a question of vital importance, and one well worthy the serious consideration of sanitarians.

The old method of draining into wells, in time became a nuisance. The difficulty of emptying them, the dangers to health that ensued from this procedure, the saturation of the soil under habitations with human refuse, all assumed such formidably objectionable features that we began to look around for some more perfect means of carrying off our sewage.

The rivers suggested themselves as natural drains, and cities located on river banks were considered blessed indeed, and into their capacious flow our waste of all kinds was made to empty, and we were satisfied that we had at last solved the problem of disposal of sewage.

But was this change a wise one? Experience would seem to answer in the negative. According to Mr. FORBES, the rivers of England have now become so polluted as to constitute a danger to the public health. That this can occur, no one can for a moment doubt. Even though a city may be drained into a river from which the water supply of said city is not derived, yet, in time, and especially if this river be subject to tidal influences, its water will become so saturated with sewage that it will constitute a large uncovered cess-pool, from the surface of which the sun's rays will absorb poisonous vapors, to be wafted over the city whenever the direction of the wind is favorable.

The fish that may be supplied to the city from such a river cannot be wholesome food.

Since, then, drainage into rivers is so dangerous, how are we to properly dispose of our refuse.

The key-note of the explanation is to be found in the pregnant sentence made use of by the priests of the Catholic church, when, on Ash-Wednesday, they place upon the forehead a small pinch of ashes, "Remember, man, that thou art dust, and unto dust thou shalt return."

The proper disposition of all the products of the gradual death of man, as well as of his body in mass after the final death, is to return it to the earth from whence it came, that it may there undergo such changes as to make it once more fit to constitute an integral portion of the human being.

By sending it out into the rivers, and possibly into the oceans, we are gradually but surely robbing our land of its necessary nutriment.

If we constantly draw on, and never deposit in, a bank, it will soon be compelled to suspend payments; so will it be with our land if it receives similar treatment. That which is injurious to animal life, human refuse, is the very pabulum intended by nature for vegetable life.

But how to accomplish this? A suction system of drainage (very excellent in theory), by which

sewage is carried off some twenty-five or thirty miles from the city, is now being experimented with in a certain section of Paris. The principle on which its theory rests is the true one, the forcible drawing of all refuse far away from crowded habitations and returning it to the soil.

Some sanitarians advocate the cremating or burning of all refuse; we can see no objection to this, provided it does not destroy its value as a fertilizer, but we fear it would impose an unnecessary extra expense in the necessary subsequent removal of the ashes.

To accomplish such a reform the people must realize its importance.

To criticise a man because he does not subscribe to your belief, seems very much like dogmatism, yet, in the matter of sanitation, any man who understands anything about it, and does not give it his hearty and active coöperation, can only be characterized as exceedingly thoughtless, to say the least.

Of all natural sciences, hygiene (sanitation), to-day, though only in its infancy, has the greatest amount of *certainty* to offer in its teachings. It can tell you, with a wonderful degree of accuracy, that if you will strictly follow its directions concerning the exclusion of sewer gas from your vicinity, and will avoid the emanations from the alvine discharges of one suffering from the disease (which really means the same thing), you *cannot* have typhoid fever; unfortunately, when you have once contracted the disease, no physician can truthfully say to you, if you do as I say, you *cannot* die of typhoid fever.

This one illustration, the moral of which can be found in the instances of all the contagious diseases, argues much for the certainty with which hygiene can promise us immunity from disease; and since it is yet in its infancy, it behooves all to encourage and foster its growth, that it may *soon* become, as it ultimately *must*, the most practically valuable of all the sciences.

—The Attorney General of the United States is of opinion that a vacancy in the office of Assistant Surgeon General can be filled by the appointment of any surgeon with the rank of Colonel.

Notes and Comments.

The Reporter in 1883.

We intend, in the year 1883, to introduce several new features into the Reporter, which will make it of increased value to readers.

Special attention will be paid to giving a series of Hospital and Clinical reports, and in the matter of news and Medical Society reports we shall arrange to have as complete and early information as any journal published.

We ask our old friends to continue with us, and beg them to bring the Reporter to the notice of their medical brethren, who do not already subscribe to it. As an inducement to this, we make our present subscribers, we mean those who have already paid for the year 1882, the following offer:—

If they will send us their subscriptions for the Reporter for 1883 and 1884, they may have the two years for $8.00.

If they will send one subscription and one new subscriber for 1883, they may have both subscriptions for $7.50.

Paris Health Report.

M. Besnier's report for the last quarter of 1881 presents many facts of interest. The early part of winter was milder than usual, but the hospital mortality was high, 3784 deaths, instead of 3075 for the corresponding period of 1879, and 709 higher than the average for the nine years preceding.

1st. Affections of the Respiratory Organs. The influence of the winter season was distinct; the mortality in pneumonia was as high as 27 to 35 per cent.

2d. Diphtheria. The prevalence of this disease was most marked in one section of the city (11th Arrondissement). The number of deaths increased from 462 for the same trimester in 1880 to 605. During the past ten years, while typhoid fever caused 13,004 deaths, and the eruptive fevers 14,100, diphtheria alone swept off 16,629 victims. During the quarter M. Archambault reports 8 cases, and M. Labric 10 cases where diphtheria was contracted at the Children's Hospital, by patients who had been admitted for other diseases. Thus in two services alone 18 victims of contagion which might be prevented.

3d. Eruptive fevers. There has been a gradual decrease in the number of cases, and instead of 356 deaths in the first quarter, there has been but 117 in the last. The number of cases of smallpox was much lower, and the mortality less marked. At the Children's hospital, out of

42 cases of measles there was 18 deaths, a terrible proportion, due to the prevalence of diphtheria in the wards. M. Besnier calls attention to the increasing prevalence of scarlet fever at Paris. From 1871 to 1880 there occurred but 951 deaths from this disease, three times less than the annual mortality at London from the same malady. But in 1880 the death rate advances from 95 (1879) to 356, and this increases in 1881, when the mortality was 452; the malignant and complicated forms have been more common.

4th. Typhoid Fever. During 1881, typhoid fever held to the excessive proportions it had assumed in 1881. The disease was more frequent and of more gravity among the male population. During the quarter there were 988 cases observed in the hospitals, with 212 deaths, a mortality of 21 per cent.

In M. Labric's service at the Children's Hospital there were 18 cases with 4 deaths, three of them due to diphtheria contracted in the wards.

The Value of Antiseptics.

In the course of the Presidential address at the meeting of the Yorkshire branch of the British Medical Association, (*Brit. Med. Jour.*) Dr. T. R. Jessop said:—

As an instance of the extent to which, with antiseptic precautions, we may pursue a cancerous infiltration, I may mention the case of a hospital patient from whom I had previously removed the scirrhous mamma, and who had now returned with such a fullness between the clavicle and the deeply indented scar as to lead me to explore for secondary disease. On opening up the axillary and sub-pectoral spaces, I found them to be literally filled with adherent and infiltrating masses of growth, as is frequently the case, out of all proportion to the pre-existing signs. For their extirpation prolonged tearing and dissection were needed, during the course of which, first of all, the pleural cavity was distinctly laid open, and subsequently the axillary artery, which had been imbedded, and, perhaps, displaced, was completely torn across, and yet, with all this, the woman was able to leave the hospital within three weeks, her wound soundly healed, and herself none the worse, apparently, for the dangers through which she had passed. And again, as illustrating the advantages to be gained by perseverance in the removal of recurrent growths, I may select the case of a lady—a patient under the joint care of Mr. Halliday, of this town, and myself—who, after having during twelve consecutive months undergone no fewer than six separate operations (including the original amputation of the breast), for the removal of cancerous nodules affecting the cicatrix, the surrounding skin and subjacent tissues and the axillary lymphatics, passed upwards of two years of usefulness, in the enjoyment of good health, now again exerting herself beyond the average of women; and then died, without any sign of outward disease, from an acute thoracic affection of short duration.

Cholera-like Symptoms in Uræmia.

Dr. H. Mallins reports, in the *Lancet*, a peculiar case that came under his care some time since, in India. A man was brought into the hospital at noon, in a state of complete unconsciousness, with severe purging and vomiting, the stools being of the rice-water character. He had been working up to nine o'clock, and while cutting grass in the sun, first felt ill. His features were pinched, surface quite cold, tongue dry, with slight brown fur. By the next morning he was conscious and able to get out of bed. Pulse 118, very weak. Respirations 32. Temperature 99.2°. Suppression of urine existed, the bladder being found empty on several explorations. Diarrhœa continued, he grew drowsy, and died two days after admission.

At the time of the occurrence of this case an outbreak of cholera was not unlikely, as cases had been reported from some stations close by. The sudden occurrence of the symptoms of unconsciousness, coldness of surface, feebleness of voice, vomiting, purging, the stools being of the rice-water character, and finally the suppression of urine, might have justified the diagnosis of malignant cholera, and in the absence of an autopsy the case would most probably have been reported as such. The examination, however, revealed a hopelessly disorganized pair of kidneys, and justified the conclusion that all the symptoms were due to uræmia. It will, therefore, be well to bear in mind the possibility of cholera-like symptoms being due to the diseased kidneys. It may be added that, contrary to expectation, no outbreak of cholera took place at the station where the subject of these notes died.

Bromo-Menorrhœa.

In the *Medical Times and Gazette*, Dr. Alfred Wiltshire applies this term to offensive catamenia. If due to chlorosis he uses iron. Pledgets of cotton wool soaked in boro-glyceride are very efficacious. In middle-aged women the offensive odor may presage commencing malignant disease. Always look for a cause, either local or constitutional.

The Rational Treatment of Catarrh.

Dr. S. Baruch read a paper on this much discussed subject, before the last meeting of the South Carolina Med. Ass. (*Transactions*), which contains many valuable practical hints. He insists that every diseased part must be seen by the eye of the attendant before medication, and again examined, to ascertain if the remedies have been applied to its entire surface. The anterior nares and a small portion of the posterior surfaces can be best reached by the atomizer; the posterior nares and vault of the pharynx by the post-nasal syringe. He uses a formula consisting of one grain of carbolic acid, two grains each of bicarbonate and biborate of soda, half an ounce of glycerine, and one ounce of water, for cleansing the parts thoroughly before applying the curative medication. *Not until every diseased and healthy part presents itself clearly*, should medication be thought of. He then recommends finely powdered arrowroot as a vehicle, and nitrate of silver, zinc sulphate, tannin, alum and bismuth as the medicinal agents. By dusting the parts well, the powder mixes with the mucus and forms a firmly adhering plasma, which slowly dissolves in the secretions, thus permitting a thorough action on the subjacent tissue. By attention to the thorough cleansing of the parts, many obstinate cases of catarrh can be made to yield to medication.

Many cases of catarrh are maintained by the habit of nose cleaning now so much in vogue. Patients should be made to learn that the delicate lining of the nasal cavities will not brook this frequent scouring without resenting it.

A Remarkable Case of Brain Lesion.

The *Revue de Méd.*, 1882, No. 5, reports the following case, which came under the attendance of Dr. Girandeau. It is one of those cases of brain lesion which would seem to prove the correctness of Brown-Sequard's views, being almost in direct contradiction to the generally adopted physiology of the brain. In a patient of middle age, motion, speech and reading were normally performed, and evinced no morbid condition. The individual simply complained of general malaise, and died of debility. The post-mortem examination gave the following result. We will mention, however, that the patient occasionally suffered from moderate headache, and that all subjective signs, as choked disk, etc., were absent.

A glio-sarcoma of the size of a walnut was found in the brain, spreading from the Sylvian fossa through the first and second third of the second temporal convolution, forward from the point of the temporal lobe three ctm., backward 1 ctm. from the lower end of the fossa Sylvii. The gyri were not pressed out of place, but were changed, up to deep into the white substance, into a rose-colored mass with hemorrhagic foci.

Here was a lesion which, from its locality, should have caused the symptoms and signs above mentioned. The case goes to show that we still do not know enough of compensatory action of the great nervous centres.

A New Sign of Pregnancy.

The *American Journal of Obstetrics* says that Jorisenne (*Arch. de Tocologie*) has furnished a sign by which we can diagnose pregnancy during the first two months. Starting with the assumption that in pregnancy there is a hypertrophy of the heart (and this assumption, if erroneous, will not affect Jorisenne's results), he has found that, while in health there is a variation of from ten to twenty beats in the radial pulsation, according as the body is upright or horizontal, in pregnancy, no matter what the position, the beats number the same. Jorisenne has been able to diagnosticate pregnancy as early as the first month, when no other sign except the missing of a menstrual period was present. When examining a patient for this sign, it is necessary to proceed with deliberation, first counting the radial for the space of fifteen seconds while the patient is standing, then sitting, then reclining. The order may then be reversed, and uniformly the same number of beats will be recorded. Jorisen promises an explanation of this phenomenon in a future paper.

Apomorphia as an Emetic.

Dr. W. Geddes Stark reports two cases in the *Canada Lancet*, one of a man who had swallowed false teeth, which were sticking in the œsophagus, the other of a woman who was becoming rapidly comatose from morphia poisoning. In each case he injected hypodermically $\frac{1}{8}$ gr. apomorphia. In the one case it provoked free emesis in six and in the other in eight minutes.

Pediculi Capitis.

In the *Brit. Med. Jour.* Dr. W. J. Beatty says that two grains of perchloride of mercury dissolved in an ounce of dilute acetic acid, well rubbed into the parts, night and morning, will effectually destroy the pediculi, and the nits formed on the hairs. The clothing should be disinfected by exposure to a temperature of at least 200° F.

Bright's Disease Treated by Pilocarpine.

Dr. S. G. Webber reports a case in the Boston *Medical and Surgical Journal.* The man's urine contained albumen, hyaline, granular, epithelial and fatty casts, blood and pus, triple phosphates and amorphous phosphates. Face and legs œdematous. Nitrate of pilocarpine, in doses of one-third of a grain, was given once or twice daily, sufficiently often to keep up free diaphoresis. He died about three weeks after admission to the hospital, when the kidneys were found to have undergone amyloid degeneration.

This case is interesting, as showing the efficacy of pilocarpine to produce its peculiar effect in exciting the sweat glands during many days of continuous use. Also its value in checking the convulsions, in preventing their return, and in prolonging the patient's life. A large amount of urea was excreted through the skin, and so much water escaped thus that the œdema disappeared. Another point of interest is that, although the urine increased to seventy-six ounces, the convulsions recurred just then.

Transplantation of Muscle in Human Beings.

Before the Imperial German Congress of Surgery, Herr Helfrich read a paper on this subject (*Medical Press and Circular*), based on a case in which the whole of the biceps of a woman had been removed, with the exception of a strip the thickness of a lead pencil, and replaced by a piece of muscle from a dog. Complete healing took place, and after some months' use of electricity, the power of movement, lost previously to the operation, was restored. Herr Gluck (Berlin) reported that his experiments in the transplantation of muscle had always given positive results.

A New Reaction for Albumen.

In the *Zeitsch. f. Analyt. Chem.*, xxi, p. 301, Dr. A. Raabe mentions the following new reaction for albumen. To the well filtered urine contained in a narrow reaction tube, a small piece of crystallized trichlor-acetic acid is added. This is gradually dissolved on the bottom of the tube, and there, where the two fluids come in contact with each other, when albumen is present, a turbid zone, clearly visible and sharply confined. Normal urine, according to R., gives no similar reaction, only if urates are present in very large quantity, a weakly turbid condition follows, but this is not confined as mentioned, but spreads all over the fluid. Further, if the urine is heated, this turbidity, due to urates, disappears immediately, while such is not the case with the turbid ring caused by reaction of trichlor-acetic acid on albumen in the urine. R. considers the latter reaction as far more sensitive and reliable than the one with nitric, or even with metaphosphoric acid. In doubtful cases, especially, it would be of great service.

Treatment of Scurvy.

A correspondent writes to the *Brit. Med. Jour.* reporting the following case :—

A young man with spinal disease had all the signs of sea-scurvy, spongy gums, etc. I ascertained that vegetables had been repugnant to him, and for a long period he had refrained from taking any. The use of vegetables and turpentine, with potash, both cheap remedies, wrought a speedy cure. I beg leave to suggest these drugs upon an extensive scale, as on shipboard. I believe alkalies more effective when not given, for internal or external use, in a state of chemical combination likely to neutralize the effect, *e. g.*, the citrates internally, or sulphur with lime externally, in the treatment of scabies. I prefer free sulphur, and it is the most reliable.

Discoloration of Skin in Diabetic Patients.

In two cases of diabetes, where the patients were not only very emaciated, but where the skin had assumed the well-known brownish discoloration, Dr. V. Hanot (*Revue de Méd.*, 1882, p. 385) found at the post-mortem examination hypertrophic cirrhosis of the liver, with pigmentation to a high degree of the liver cells, and also strong pigment masses in the interstitial spaces.

So far, this peculiar discoloration of the skin in diabetic persons had been unexplained, and therefore the above observation is rather of decided importance.

Perforation of the Ileum by Worms.

Dr. T. J. Crofford reported, at the last meeting of the Mississippi State Medical Society, the case of a boy (colored), aged eight, who complained of pain in the right iliac region, had fever for eight days and died, having passed several round worms three days before death. At the autopsy the ileum showed two perforations, one twelve, the other twenty-four inches above the ileo-cæcal valve, and the peritoneal cavity contained half a pint of pus and two lumbricoid worms, each ten inches long. One of the worms was between the liver and diaphragm, partially decomposed. The edges of the perforations in the bowel were covered with lymph.

Correspondence.

Ante-partum Hour-Glass Contractions, Complicated with Hydrocephalus.

Ed. Med. and Surg. Reporter :—

On Sept. 3d I was called to attend Mrs. W. S., thirty years old, five feet high, weight 115 pounds, in her fifth confinement. I had attended her in her last two confinements. Nothing unusual. Her health tolerably good. She had been in labor about twelve hours when I arrived at the house, at six o'clock P. M. Applying my hand to the abdomen, to determine the probable presentation, I was astonished to find the upper segment of the uterus contracted as hard as a stone, the lower segment apparently normal and but slightly contracted during pain.

Upon making an examination per vaginam I found the os more than half dilated, the membranes completely filling the opening, and the os soft and dilatable. By the most critical examination, I could find no part of the child presenting. After waiting about two hours and finding no progress had been made, I ruptured the membranes and discharged an immense quantity of water.

In a short time I found the left shoulder presenting at the right of the middle of the sacrum ; the right shoulder, above the right acetabulum ; the head turned back, with the occiput lying on the upper dorsal vertebra ; the neck, of course, broken. Believing I had an extraordinary and difficult case, I sent for assistance and chloroform. When my assistant (Dr. Freeman) arrived, I put the patient under the influence of chloroform, and proceeded to perform version.

Passing my right hand into the uterus, it came in contact with an enormous head, filling its lower segment. With difficulty I passed my hand around the head, as high as the umbilicus, when I came in contact with an hour-glass contraction, about one inch above the middle of the uterus. It resembled, to the touch, a hard rubber ring, about one and a half to one and three-fourths of an inch in diameter ; its internal surface as smooth as glass and about one-half an inch thick. With difficulty, and after thirty minutes' time, I succeeded in passing my hand through the ring, as far as a little above the knuckles. I was then, from pain and exhaustion of my hand, compelled to wait some time, to recover from its half paralyzed condition.

I then slowly closed it, to dilate the ring, which gradually yielded to the pressure, and, extending my fingers, I passed them over the nates (the fundus remaining in the same rocky condition), and along the left thigh, until I reached the popliteal space. Then flexing the thigh upon the abdomen, I commenced direct traction. During this part of the operation I suffered most severely from the pain and exhaustion of my arm and hand.

By persistent traction I gradually brought the legs through the ring, and in time, the breast. As the breast emerged from the ring, the whole body of the uterus contracted uniformly, and assisted me greatly in bringing down the body of the child. Suffice it to say I succeeded in delivering the body and arms. I then attempted to bring the head into the pelvic cavity, and, applying too much force, ruptured the muscles and tissues of the neck above the right clavicle, thus disclosing the cervical vertebræ, examining which I found the fifth vertebræ separated from the fourth from an inch to an inch and a half, and a portion of the cord, thin and shriveled, protruding from the fourth.

It occurred to me that I could utilize the accident by forcing the water from the head through the spinal canal. The head could now be distinctly outlined (in the absence of pain), reaching to the umbilicus.

Upon making firm pressure on the head, through the abdominal walls, I was much gratified to see the water rapidly issuing from the wound in the neck, until all but about four ounces was discharged.

By traction upon the remaining tissues of the neck, and with the aid of the blunt hook placed over the ramus of the jaw, by my assistant, I succeeded in delivering the head in about twenty minutes. There was neither hemorrhage nor laceration of the soft parts. Placenta came away in three minutes. Patient made a good recovery, and is now attending to her usual household duties.

Time of operation, one hour and forty minutes.

Tideoute, Pa.

Malaria in Skin Diseases—a Correction.

Ed. Med. and Surg. Reporter :—

Some time since the following paragraph appeared in the *Michigan Medical News*, and has been widely copied in the medical journals of the country :—

"A century ago John Hunter divided all skin diseases into three classes, one of which is cured by mercury and the iodides, a second by sulphur, and a third class which the devil himself can't cure. Dr. L. P. Yandell, who quotes Hunter as above, is given credit for a much less complex classification than even this. He attributes all skin eruptions to malaria. Quinine is a specific for malaria: ergo, quinine is the remedy for all skin eruptions. Q. E. D."

I trust that my confréres of the press will do me the kindness and the justice to publish the correction now given, as the matter is not only one of personal interest to the writer, but is of scientific interest to the profession. The subjoined extracts are from a supplement to a report read to the American Dermatological Association, September, 1877. A copy of this report will be gladly sent to any one desiring it :—

"From the criticisms which have been made on my views, I find that I have not succeeded in making myself perfectly understood. What I have contended for, and what I have reiterated, is simply this: Malaria is *the chief source* of *acute* skin disease. Scrofula is *the chief source* of *chronic* skin disease. The more inveterate cases of skin disease are often due to the coexistence of these two things. The specific exanthems, of course, are not included here, but I contend that their progress and termination are often largely influenced by the presence of mala-

ria, or struma. *I do not claim* that malaria and struma are the *sole* causes of the dermatoses. Indeed, *many* of the dermatoses may exist *independently* of *malaria* or *struma*, and most frequently some exciting cause is necessary to develop the cutaneous eruption. Among the exciting causes are irritants, injuries, insufficient or improper ingesta, vicissitudes of temperature, alcohol, dentition, menstruation, parturition, lactation, etc. The proofs of the truth of my views are, in the first place, that the diseases of the skin are cured more certainly and more quickly by the anti-malarial remedies on the one hand, and by the anti-strumous on the other, than can be done by any other line of therapeutics; and in the second place, that careful and painstaking investigation will, in the majority of dermatoses, make apparent the existence of the malaria or the struma, as the case may be.

"In conclusion, I desire to impress upon the reader that my views are not confined to the skin diseases. What produces disease here will produce it in all other organs of the body. What is true of dermatology is equally true of gynecology, and ophthalmology, and otology, and it is just as true of the diseases of all the other regions of the body."

Subsequent observation has confirmed my belief in the correctness of these views.

LUNSFORD P. YANDELL, M.D.

Conjugal Onanism.

ED. MED. AND SURG. REPORTER.

Soon after the publication of "Goodell's Lessons on Gynæcology" I purchased a copy of the book, and have frequently referred to it in my practice, with great benefit to myself and patients.

I have often read with close attention the last chapter in the book, on "The Sexual Relations as Causes of Uterine Disorders." I have, again, just finished the perusal of this chapter. I entirely dissent from the author's theological opinions therein set forth. It is hardly an open question whether those views are in place in such a work, and I have never been able to refer any of the evils which he so eloquently portrays to the cause to which he ascribes them. I am inclined to think that his theology has obscured his otherwise remarkably clear and practical mind. However this may be, and no matter whether he or I am right or wrong, the subject presented in the chapter referred to is of sufficient importance to entitle it to a thorough examination in the columns of the REPORTER, if not from a theological, at least from a medical standpoint.

The question, then, which I would like to have discussed in the REPORTER is: Is the moral and physical degradation resulting from these vicious sexual relations (viz. conjugal onanism and other preventive measures) so damaging as Professor Goodell represents them to be, or is it not. There is little if any occasion to doubt that these preventive measures are very extensively practiced at the present day, throughout this and all other *bible reading* countries.

It becomes, then, the duty of all physicians to inquire carefully into the damaging charges laid to these practices. No "squeamishness" should close our lips, and no theological bias should blind our eyes or prejudice our minds, in investigating this subject. If I shall succeed in arousing a spirit of investigation in regard to this very important question among the profession, my object in writing the above will have been attained.

H. NYE, M.D.

Enon Valley, Pa., Nov. 20th, 1882.

NEWS AND MISCELLANY.

Dr. Oliver Wendell Holmes' Farewell.

On Tuesday afternoon, Nov. 28, Dr. Oliver Wendell Holmes took formal leave of the Chair of Anatomy in the Harvard Medical School, which position he has held for thirty-five years. After the applause which greeted his entrance to the lecture room had subsided, the Professor said there were three times in a man's life when he might consider himself the centre of attraction, at his christening, at his marriage, and at his own funeral. This, the beginning of his thirty-sixth course of lectures on anatomy, was the end of his connection with the school. For about half of this time he had also taught physiology, but with the growth of the science he had gladly given it over to form a new department. It was a good thing for a college to get rid of her old men. Their ideas were antiquated, and the college had better let them go. He had held his office so long because he taught a subject which could never become antiquated. In his lifetime it had received very important additions. He had begun the study of law in his youth, as an experiment, but for various reasons had turned his attention to medicine. While in the Law School he had engaged with some friends in publishing a paper, and for the first time saw himself in print. From the printers' type he had contracted the disease of authors, lead poisoning, which he had never quite got rid of. The Doctor finished with some practical remarks on the way in which the science was tending.

Dr. Holmes is to be made Professor Emeritus of the school. The Doctor, it is understood, resigned the professorship not because of ill-health or old age, but because he wishes to devote more time to the field of literature.

National Board of Health Report.

The National Board of Health has filed its report for the fiscal year 1882. One of the sections of the law of 1879 imposes penalties on ships which enter a port of the United States from an infected foreign port, but the Board has found this part of the law inoperative, inasmuch as one of its clauses requires the promulgation of the law in the foreign ports, and the authorities of Cuba would not permit this promulgation to be made. It is, therefore, strongly urged in the report that this law be so amended as to require bills of health from all vessels coming to the United States, without imposing upon this Government the burden of proving their ports of departure to have been infected, and also that the penalties provided for the violation of the

law should apply without the proviso of a previous official promulgation in the said ports. We cannot too strongly second this recommendation. The health and lives of the people must be paramount to every other consideration, and when it has been demonstrated that a place like Cuba (from which much of our yellow fever comes) can, by obstinacy, interfere with our sanitary arrangements, then we should so legislate as to take from her or any other country this obnoxious and dangerous power. The report, after showing that all the work undertaken and carried on successfully by the Board was clearly within the limits of its discretion under the law, and was accomplished with due regard to economy, closes with estimates for the continuance of its work, amounting to $150,000, with an epidemic contingent fund of $100,000.

A Worthy Example.

A beautiful memorial of his daughter, who died last summer, has been made by Senator Edmunds, by endowing in her name a room in the Mary Fletcher Hospital, Burlington, Vermont. Over the door, outside, a handsome tablet bears the name, "Julia M. Edmunds," and the date of the endowment. Within, the room is luxuriously furnished, every article in it being marked with the initials "J. M. E." On the wall hangs a superb engraving of Millet's painting, *L'Angelus*. The endowment, $5000, provides for the support and care of one free patient, and its first beneficiary has just been received.

Practical charity is not so common in this country but that so beautiful an example of it should be given extensive notoriety. No one could erect a more lasting or pleasing monument to the memory of a dear departed one than by following this worthy example. Our hospitals are none too rich, and such munificence would enable them to dispense even more charity than they do at present.

Cremation in France.

A bill has been distributed in the Chamber of Deputies containing, among other signatures, those of M. Gambetta and M. Paul Bert, giving all persons the right to leave testamentary instructions as to whether their bodies shall be buried or cremated.

This seems like a very fair way of legislation; to allow a man to do what he pleases with his own body. While cremation possesses many advantages over the ordinary mode of burial, yet we have always felt that it interfered to a certain extent with the economy of nature, "*dust to dust*," etc.

Dwarfs.

Anna Minerva Shearer, the child monstrosity, an object of curiosity to thousands of visitors, died at her parents' home, Stonersville, near Reading, Pa., Nov. 26. The child was ten years of age, and weighed fourteen pounds; was blind all her life, and unable to walk or talk. A sister, aged thirteen years, weighs twenty pounds, and is in the same condition. The parents are full grown, healthy, and strong, and the father is a blacksmith. The children's only sense was that of hearing, and they had to be attended to like infants.

A most interesting study would be in the direction of the causation of such seemingly inexplicable phenomena. Whether it were due to some peculiar moral condition of one or both parents at the time of conception, or to some subsequent influence acting on the early embryo.

The very intricacies and difficulties in the pursuit of the subject would make it interesting to some investigators.

German Scientists.

Much to our surprise we note the following item in the *Chemist and Druggist*:—

How scientific attainments are rewarded in Germany may be judged from an advertisement which the *Chemiker Zeitung* quotes from a journal devoted to the sugar industry in Germany. The services are required of an "academically-educated chemist, fully acquainted with the manufacture (sugar), who can undertake in summer the *coppersmiths' work*, or the oversight of the *teams of draught oxen*."

We were under the impression that science was highly prized in Germany, and that true scientists were thoroughly appreciated. Perhaps the sugar making concern in question was of such a class that the "*academically educated chemist* suitable for them would have more knowledge of oxen than of chemistry.

Prang's Cards.

The cultivation of a correct taste for color and form adds vastly to the enjoyment, and, we are not afraid to add, to the nobility of life. One of the most praiseworthy efforts in this direction is that of Mr. Prang, of Boston, who has offered large sums as prizes, for the best *Christmas card designs*, which he published in chromo-lithography, with appropriate original verses from our most distinguished poets. The idea is altogether an admirable one, and if any of our readers are at a loss what to buy for a Christmas present for old or young, married or single, rich or poor, they cannot go amiss in making the very small investment required, from 75 cents to $1.25, for one of these charming designs in colors. For catalogue and particulars, address L. Prang & Co., Boston, Mass.

Precautions Against Diphtheria.

The committee, appointed by the Board of Health of this city to draft a circular containing precautionary measures against the spread of diphtheria, have made their report. They recommend the usual methods looking toward isolation and disinfection. In particular we note two very good suggestions. 1st. To remove the patient to that room in the house that is furthest away from the inhabited portion; and 2d. To avoid inhaling the breath of or kissing any one who has a sore throat, during the prevalence of the epidemic.

This last suggestion is a most important one.

Promiscuous kissing has been infinitely more productive of disease of various kinds than the public ever dream of, and it is a practice that should be discountenanced. The people should confine their kissing propensities to members of their own families, and even then it is not always safe.

A Prolific Family.

The *New England Medical Monthly* records the following case:—

Among the papers of the late Thomas Atwater, of New Haven, Conn., the following memoranda were recently found:—

"Mrs. Mabie, No. 100 Twenty-ninth street, New York, of the firm of Topping & Co., has been married forty-eight months.

July 24th, 1858, had	1	child.
July 30th, 1859, "	2	children
March 29th, 1860, "	2	"
March 4th, 1861, "	3	"
Feb. 13th, 1862, "	4	"
Total	12	"

These children were all born within three years and seven months, and are all living and healthy. This is a copy from a memorandum given by the father, Mr. Mabie.

Anecdote of Jenner.

Dr. Jenner was a man of wit, and the following lines addressed to a lady upon the recovery of her daughter, and sent with a pair of ducks, afford a specimen of his facetious vein:—

"I've despatched, my dear madam, this scrap of a letter,
To say that Miss —— is very much better;
A regular doctor no longer she lacks,
And therefore I've sent her a couple of quacks."

Faith Cure.

A woman of Windham county, Connecticut, was afflicted with a chronic disease of the nerves. She got herself into such a state that she "believed God would hear and answer," and then prayed to be cured. The Danielsville *Transcript* says that her recovery is complete, and adds: "The present generation hasn't squeezed the orange of either material or theological knowledge."

Another illustration of the power of imagination, especially in hysterical women. We do not mean to say that God has not the power to work miracles, but we do believe that they are seldom so manifested.

An Infant Killed by Rats.

One day recently a family out in Kentucky went to church, leaving an infant in the care of a colored girl. She also went away leaving the child on a pallet on the floor, and when the family returned the baby was dead and horribly mangled by rats. Physicians should impress upon mothers, the great danger of leaving babies and young children alone. We have known many instances where serious and even fatal results have occurred from children drinking poisonous medicines when alone.

Garfield's Physicians.

The Garfield Board of Audit has filed its report at last. Dr. Bliss gets $6500; Drs. Agnew and Hamilton each $5000; Dr. Boynton $4000, and Mrs. Dr. Edson $3000. Though very slow about it, we must congratulate the Board on what seems to us a very fair adjudication of these very large claims.

Dead at 115 Years.

The daily papers report the death in this city, on Nov. 28th, of a colored woman, said to be 115 years old. While there was no positive evidence that she had attained this great age, yet it was generally credited by her family and we can see no reason to doubt it, since such great age is very possible.

Items.

—Dr. Edwin R. Maxson recently read a very interesting paper on "The Microscopy of Nutrition," before the Microscopical Club of Syracuse, N. Y.

—Dr. Janeway reports three cases of aneurism of the arch of the aorta in which the first symptom attracting attention was cervico-brachial neuralgia.

MARRIAGES.

DIEHL—WILLIAMS.—On the 11th of October, at the residence of the bride's parents, by Rev. C. W. Bickley, Dr. Oliver Diehl and Miss Sarah H. Williams, all of Phila.

ERWIN—McDOWELL.—In Mercersburg, Pa., October 12th, by Rev. H. G Mendenhall, Dr. A. J. Erwin, of Mansfield, O., and Martha B. McDowell.

EWING—MILLS.—On October 11th, by Rev. John Jay Pomeroy, assisted by Rev. James D. Wilson, D.D., William A. Ewing, M.D., of New York city, and Matilda S. Mills, of Rahway, N. J.

HAZARD—RICE.—At the residence of the bride's father, in Newport, Ky., on Wednesday, October 25th, by the Rev. John Hugh Ely, assisted by the Rev. Mr. Stewart, J. Henry Hazard, M.D., of Cincinnati, and Miss Mary Thorp Rice.

HUNT—STECK.—In Brookville, Pa., October 3d, by Rev. Thomas J. Sherrard, assisted by Rev. Theodore Henderson, Robert M. Hunt, M.D., and Mrs. Rachel M. Steck, both of Brookville.

PALMER—ECKELS.—In Princeton, Ill., October 19th, by Rev. M. C. Williams, Charles A. Palmer, M.D., and Jennie J., daughter of James S. Eckels, Esq., all of Princeton.

SANTEE—MONTELIUS.—On October 19th, at the residence of the bride's father, in West Philadelphia, by Stephen W. Dana, D.D., assisted by Alfred Yeomans D.D., Eugene I. Santee, M.D., and Mary Alice, daughter of William Montelius, all of Philadelphia.

SCHAFFER—ZOOK.—On Wednesday, Oct. 25th, at the Walnut Street Presbyterian Church, by the Rev. S. W. Dana, D.D., Charles Schaffer, M.D., and Ellen E., daughter of the late Major David Zook.

DEATHS.

FRISBY.—In this city, on Oct. 31st, after a lingering illness, Dr. S. Clarke Frisby, aged 33 years.

KING.—On Thursday, Nov. 9th, 1882, Kenneth K. King, M.D., aged 32 years.

McCOY.—In Doylestown, Nov. 7th, of apoplexy, Dr. Gilbert R. McCoy, in his 67th year.

RICKARDS.—In this city, on Nov. 13th, Elias S. Rickards, M.D., aged 84 years.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., PHILADELPHIA

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1

EXCISION OF THE WOMB, WITH FIBROID TUMORS.

BY J. M. F. GASTON, M.D.,

Of Campinas, San Paulo, Brazil.

I have to report a case which has been under my observation, the immediate charge of a colleague, of this city, Dr. Germano Melchert.

When first examined there were discernible through the abdominal wall, in the hypogastric and iliac region, three separate protuberances, evidently forming parts of one tumor; and upon extending the exploration through the vagina, it was ascertained that the os uteri was raised above its ordinary level and to the right of the median line, while the examination by the rectum revealed a mass projecting into the hollow of the sacrum, below the promontory of this bone, and kept in this position firmly, so as not to admit of being elevated by pressure of the fingers.

The diagnosis was that of uterine fibroids, and the woman, a mulatto slave of thirty-seven years, of rather delicate constitution and slim proportion of frame, was in a state of comparative good general health, with regularity in quantity and period of the menstrual flow. It was, therefore, agreed to put her upon a course of alteratives and tonics, with the hope of arresting the progress of the tumor. But after nearly a year of treatment, this was not found successful, and another minute examination was made by us, with the assistance of another colleague, Dr. F. Pereira Lima, who concurred in the diagnosis already made as to the nature of the tumor, and as to the indications for an operation.

The tumor now extends upward to the line of the umbilicus, and occupies the entire pelvic region, the lower portion resting in the concavity of the sacrum and thrusting the womb upward and obliquely, so that the os uteri is found immediately behind the imaginary line of division of the iliac and pubic bones, and pressed up against the bony rim of the pelvis, so as to nearly occlude the aperture of the neck of the womb. It was found impracticable to pass the sound into the small orifice of the external os; and it was left to conjecture as to the direction of the axis of the canal of the cervix and the position of the body of the womb, as there remained no practicable mode, in the absence of sounding, for ascertaining these points, except by inference from the displacement of the os uteri.

As it was expected that extirpation of the entire body of the organ with its appendages would be requisite, every preparation was made in advance for this operation, and on May 20th, 1882, it was undertaken by Dr. Germano Melchert, with the assistance of Drs. Pereira Lima, Antenor Guimaraes, Benedicto de Lonza, and myself. As I had the opportunity of witnessing some operations by Dr. J. Marion Sims and Dr. Nathan Bozeman, in ovariotomy, two years ago, and neither of my colleagues present had ever seen anything of abdominal surgery, it devolved upon me to guide in the operation as to the different steps of the laparotomy, and consequent ligation and excision, with the special provision for drainage and closure of the external wound. As my medical friend in whose infirmary the operation

was to be performed wished to avoid even the appearance of neglect, he had a carbolic spray apparatus at work in the room for an hour previous to the entrance of the patient, but it was stopped before even the chloroform was administered, and not resumed during the progress of the different steps of the operation.

The abdominal incision was made in the median line, extending from an inch above the os pubis to within an inch of the umbilicus, from which an effort was made to extract the indurated mass, but this being found impracticable, the incision was extended up and to the left of the umbilicus, until it extended to an inch above it. The entire nodulated tumor, with the womb located diagonally upon its anterior and lower face, and the Fallopian tubes with the ovaries, being now dislodged, a transverse incision was made above the cervix and the investing peritoneal coating was peeled off and left continuous with the upper surface of the bladder. The exact site and relations of the latter organ were defined by a catheter passed through the urethra and held by one of the assistants, while this most delicate step in the whole proceeding was executed.

In accordance with a previous understanding a tube was in readiness to pass up into the canal of the cervix, if this should be found practicable; but upon making the exploration with a long silver male catheter, the construction of the cervix was such as not even to admit this, and hence this measure had to be reluctantly abandoned. Strong silk ligatures were passed, with a needle, around the neck of the womb, which was not at all involved in the fibroid growth, and around the tissues upon either side, secured in three loops by three separate knots drawn as tight as was admissible without laceration. Yet, to afford additional security against the much to be feared secondary hemorrhage, a strong silk cord, consisting of four large silk ligatures twisted together, was thrown around the whole, upon the distal side of the ligation already made in three segments. The operator now thought there could be no doubt about using the knife or scissors to divide the pedicle, but realizing, from my study of these cases that every caution that can be observed is not too much, the ecraseur was advised and adopted for the excision, while the fingers of assistants were kept between the line of the chain and the strong cord that circled the entire pedicle. No part of the fibroid mass remained with the pedicle, and there was no indication of any hemorrhage from the incised surface. Some small coagula that had formed from the blood that entered in the dissection of the anterior peritoneal investment of the womb, were removed from the cavity, and a large sponge introduced, which had been wrung out of a ten per cent. carbolic solution, by which the remaining sanguineous effusion from the early steps of the operation was removed, and the cavity was carefully wiped out with old carbolized linen cloths, until there was scarcely a stain left upon them. There was but one opinion on the part of all present in regard to the further management of the case.

As to the disposition of the several ligatures, all agreed that both extremities of each should be retained, and reunited in one cord, to be brought out at the lower part of the abdominal incision jointly with a carbolized rubber drainage tube of the calibre of one-fourth of an inch. This being done, and waiting for a few minutes to observe whether there were any indications of hemorrhage, of which none appeared, the inner peritoneal membrane was closed by six interrupted catgut sutures, and cut off close to the knots, with a view to leave them for absorption. The external incision was closed with six silver wire ligatures, passing deeply into the subcutaneous tissues, but without penetrating the peritoneal coating. Three points of silk ligature were used to unite the curved line around the navel. Before applying the external dressings the patient was turned carefully upon her left side, with the drainage tube and cord of ligatures lying upon that side, while moderate uniform pressure was made upon each side, and yet not a drop of blood appeared at the lower angle of the incision.

The external applications consisted of carbolized lint over the entire abdomen, covered with carbolized cotton, and this protected by the impermeable cloth, all being secured by a moderately firm bandage.

The dressings being complete, and the effects of the chloroform having disappeared, the patient was removed from the operating table to a bed in the same room. The temperature being taken half an hour afterwards, it then being 2.30 P. M., was found to be somewhat below the normal standard, registering 36.5 by Centigrade thermometer. Observing the pulse at the same time, it was found to be feeble and accelerated, giving 120 beats to the minute. Brandy was given and afterwards aqua ammonia, without improving the circulation, and brandy was resorted to by subcutaneous injection, to no effect. The hypodermic application of quinine and morphine was not attended with any perceptible change for

the better, and thinking we had to deal with the overpowering collapse of shock, the interrupted current of electricity was used assiduously, from the præcordial region to the extremities, and from the back of the neck to different parts of the body. Our patient was now pulseless and without power to swallow or to speak, and it seemed that a very slim hope remained for resuscitation. Friction, hot bottles to the extremities, etc., etc., all seemed of no avail.

In the midst of this, it was discovered that all the dressings were saturated with blood, and we realized that though the enemy appeared in a different form, it was likely to be quite as serious as the dreaded element of general nervous prostration involved in the idea of shock. It was in some respects, however, a relief to combat a new phase, originating from a source that admitted of connection, however remote might be the prospect of relief. The dressings were removed from the surface of the abdomen, and substituted by cloths wrung out of cold water and repeated every few minutes. Beef tea with brandy was given as soon and as often as she could be induced to swallow, and ultimately the strong beef soup was used as an enema. The blood continued to discolor the cloths for the space of several hours, but in diminished quantity. The temperature was taken again at half-past six in the evening and was 37.2 Centigrade.

May 21st. Upon visiting the patient early in the morning, it was found that some discharge of blood still continued, and that while the pulse was perceptible, the prostration was marked. She complained of nausea, and vomited while I was present, being evidently the accumulation of fluid ingesta. Fresh, sweet milk and brandy were advised, and to continue the enemata of beef soup. Upon inspecting the dressings after the retching, it appeared that the sanguineous discharge that was forced out was not a recent flow, but had been retained and mixed with serous collections in the cavity of the abdomen. This encouraged a hope that the hemorrhage might become permanently checked. Speech still quite indistinct.

At my mid-day visit it was found that all the wet cloths had been removed, and that the antiseptic dressing had been reapplied by the surgeon in charge, and that no blood whatever had escaped for several hours, nor had the patient vomited any more.

The urine being drawn off by the catheter, presented nothing abnormal in quantity or quality, giving thus assurance that the ureters had suffered no violence by the steps taken in the operation. Labarraque's wine prescribed.

Upon visiting the patient in the evening, the exudation by the drainage-tube and the capillary conduction of the cord of ligatures did not indicate fresh hemorrhage, but still served to moisten the lint immediately around the opening with the sanguineous discharge. She had vomited again late in the afternoon, and complained of acidity and burning in the stomach, so that it was agreed to give her occasionally a small quantity of a mixture with bi-carbonate of soda, laudanum and peppermint. The extract of beef, made by filling a large-mouthed bottle with the small pieces and placing this in another vessel with boiling water, until thoroughly cooked, was recommended in conjunction with port wine. The enemata of beef soup to be continued. Her pulse continues so weak as not to be counted at the wrist, yet there is not so great prostration of the physical powers, and she speaks audibly and intelligently when addressed. The lower extremities are as warm as natural. Temperature at 9 A.M., 37°; at 2.30 P.M., 36.7°; at 6.30 P.M., 37°; at 10.30 P.M., 36.7° Centigrade. This scale, being in use here, can be transferred to Fahrenheit.

May 22d, was called before daylight by my colleague, Dr. Melchert, to assist him in reducing a small omental hernia that had occurred immediately below the umbilicus, where, inadvertently, a space had been left between the silver wire suture and the points of silk that were used in the curved incision around the navel. By removing one of the loops of the silver wire the protrusion was readily reduced, and as it presented no signs of strangulation or inflammation, it is hoped that this accident may not seriously complicate the result. In the space where the hernia occurred, three points of silver sutures, penetrating all the tissues of the abdominal wall, were made to substitute the one removed, and another inserted on a level with the navel.

The patient has lost but little blood during the night, and her general condition is more promising, though the pulse is barely perceptible; her extremities are of natural temperature, while her speech indicates more strength. The extract of beef, with wine, has been acceptable to the stomach, and she has vomited but once.

Before mid-day I was summoned, according to appointment with my colleagues, and found for the first time since the afternoon of the operation that the pulse could be counted, being 140 per minute, and yet very feeble.

The urine, which had remained for twelve

hours, was drawn with the catheter, and measured twelve fluid ounces, it being understood that in the future it should be removed every six hours. The vagina was washed out with a tepid carbolic solution, presenting some mucous discharge in the fluid that was returned. The abdominal cavity was thoroughly cleansed with a two per cent. carbolic solution, in a large syringe, by passing a female catheter along the side of the drainage tube, through which and by the opening around it, the fluid mixed with blood flowed out. At first it was highly colored, but upon the third repetition of the injection it returned only slightly tinged with blood. This was done with the patient upon her right side, and she was afterwards put upon the left side, so as to drain out all the fluid. The antiseptic dressing was then re-applied with the patient resting upon her back, and she dropped asleep soon afterwards, being apparently free from pain. It was agreed to give a pill of two grains of sulphate of quinine with four grains of ergotine every two or three hours, and to use an injection into the vaginal canal of a strong solution of tannin and ergotine occasionally, according to the amount of hemorrhagic discharge from the incision. Nourishment to be urged to the extent that it may be well received by the stomach, and continued by enemata.

At the evening visit the lint next the incision is found soaked with blood, after having been changed during the afternoon, so that it is very evident that the hemorrhage is not arrested. But the styptic vaginal injection, though in the room, has not been applied, and a hope is entertained that its use to-night may yet prove advantageous. The pulse is more distinct, and counts 138 to the minute. The extract of beef with wine has not been rejected, though she has had nausea occasionally. She has taken the pill of quinine and ergotine regularly during the day, and the urine was drawn off in the afternoon, being nearly as much as in the morning. Temperature at 9 A.M., 37.8, at 2 P.M., 37 at 10.30 P.M., 37.8, Centigrade, indicating a slight increase from yesterday's record.

May 23d. Examined at 9 o'clock A.M., the pulse counted only 120 to the minute, and the lint which had been applied over the incision at 9 o'clock last night was only moistened with blood immediately around the aperture at the lower angle, none having run out at the end of the drainage tube below.

The mixture of 3 drachms of ergotine and 1 drachm of tannin in 12 ounces of water was applied in the vagina and in the rectum last night, and seems to have had a marked effect in restraining the hemorrhage. There is slight distention of the large intestines, causing tympanites and some increase of sensibility over the lower part of the abdomen; yes, there are most clear indications of peritonitis. The urine has increased in quantity, and though it had been drawn off only three hours previously, there was passed by the catheter ten ounces of urine at this time. Upon washing out the cavity of the abdomen with the two per cent. carbolic solution, the contents of the first syringe returned colored deeply with blood, but upon using the third there was only a slight reddish tinge of the water.

The astringent injection within the vagina and rectum was repeated this morning. It was understood that she should take an ounce of castor oil with a drachm of spirits of turpentine, to-day, to relieve the bowels.

At night the medicine had not acted upon the bowels, and the distention was much increased, especially in the epigastric region and hypochondriac, corresponding to the curve of the colon. An elastic tube being passed up through the rectum to the distance of eighteen inches caused no escape of air, and hence the impression that the tympanic condition resulted from intestinal flatus seems not to be founded in fact. Castor oil and warm water were thrown up into the colon, but without producing evacuation from the bowels, and a repetition of the oil and spts. turpentine was ordered internally.

The pulse continues at 120 beats to the minute, and the flow of urine is so abundant as to necessitate being drawn every three or four hours. Having passed five hours this afternoon there was an accumulation of twelve ounces of urine. The vaginal canal was washed out with a tepid two per cent. carbolic solution and a portion of the astringent mixture was injected afterward.

There has been some blood discharged from the lower angle of the incision, yet the quantity is less than on the previous days, and the strength of the patient has not been affected by it. A strong camphorated turpentine liniment was passed over the whole of the distended abdomen with the lint over the incision saturated with carbolized oil, and outside of this was placed the cotton batting with the oil silk to cover the whole. Temperature at 9 A.M., 37.5, at 4 P.M., 38.2, at 9 P.M., 37.8.

May 29th. At 8 o'clock A.M., found the pulse still with 120 beats to the minute and with more volume than yesterday. The distention continues very marked in the epigastic region, with tympanic resonance upon percussion, and can

only be explained upon the supposition of air in the stomach. The abdominal tenderness has not increased, but the hemorrhage continues to moisten the lint around the opening at the lower angle of the incision within three or four hours. With the second dose of oil and turpentine no effect was produced, and a full dose of citrate magnesia had a very slight action upon the intestines in the latter part of the night and this morning.

The two per cent. carbolized wash was less tinged with blood than on any previous occasion, and in turning the patient from side to side, with gradual pressure over each side of the abdomen, there was not so much complaint of soreness as yesterday. The vagina was also washed out, and the mixture of ergotin and tannin injected, leaving a portion in the canal. Assafœtida and ether, with fennel seed tea, is to be used, with a view to dislodge the gas from the stomach, which organ is evidently relaxed and distended, with a tendency to decomposition.

Upon visiting the case in the evening, it was found that free alvine evacuations had ensued during the afternoon, and the patient had also vomited immediately previous to my entrance, which had caused a considerable increase of hemorrhage, with the florid hue of fresh arterial blood, the pulse being somewhat accelerated, so that it beat 126 to the minute. The general condition indicated more prostration, and there was slight perspiration over the surface of the body. The urine having been drawn every three or four hours, yielded on this occasion about eight ounces, which presented its normal appearance. Being called to see her again about 9 o'clock at night, there had been no further hemorrhage, though vomiting had occurred on this occasion also, and the pulse had resumed the standard of 120 to the minute. Upon a careful examination of the abdomen it was now observed that the tympanitic condition extended in a slight degree below, and continued in a less degree throughout the epigastric and hypochondriac region, without any increase of sensibility to the touch.

The pill of ergotine and quinine, which had been suspended on account of the indications for the assafœtida and ether, were resumed, with the addition of a capsule of spirits of turpentine every two or three hours. Chlorodyne was applied over the distended epigastric and hypochondriac regions, with a view to exercise compression, and thus restore tone to the internal parts, if the tendency to disintegration can be stopped. Temperature at 9 A. M. 37.2, at 3 P. M. 37.7, at 9 P.M. 37.5.

May 25. At 8 o'clock in the morning found the patient with a very feeble pulse of 125 per minute; anxious, careworn expression of countenance, enlargement of the whole abdominal region, but less tympanitic distention of the epigastric region, with the aperture in the lower angle of incision gaping, and exuding a sanious discharge. There has been no further hemorrhage, and the diminished sensibility upon any pressure around the incision is significant of a loss of vitality. She has not vomited this morning. The urine continues without change in quantity or quality. After washing out the cavity with the carbolized solution, simple warm water was used, preparatory to an injection of solution of permanganate of potash, having the strength of one-half of one per cent. This returned without appearing to be decomposed by contact with the tissues. A large poultice, with Peruvian bark, camphor and charcoal, was laid over the abdomen, and to be renewed, from time to time, as a corrective. Decoctions of Peruvian bark, with tincture of nux vomica and carbonate of ammonia, to be alternated with the wine of Labarraque, hourly. The prognosis is, of course, most grave, in view of the gangrenous features, and yet nothing should be left undone in the treatment. Temperature at 7 A. M. was 37.8 Centigrade.

The patient gradually declined, and died at mid-day.

The autopsy was made at 5 o'clock in the afternoon, by Dr. Melchert, and myself, with the presence of Dr. Antenor Guimaraes and Dr. Bento de Lonza.

Upon removing the interrupted suture of silk above the navel and of silver wire below, the entire line of incision opened, showing that no adhesion had been effected in any part, either of the skin, the subcutaneous tissue, or the peritoneal membrane.

The entire intestinal canal was filled with air, and the stomach enormously distended, as a result of the decomposition.

Adhesion had commenced in various parts between the investment of the intestines and the lining of the lateral walls of the abdomen. There were present in the lower posterior portion of the abdominal cavity, diffused among the coils of the small intestine, on either side of the lumbar vertebræ, signs of half decomposed blood. The lining membrane of the abdomen in these parts especially gave indications of discoloration, and the entire peritoneum was more or less engorged, and afforded evidence of the

inflammatory process that had been developed. Removing the stomach and intestines, a considerable accumulation of sanguineous fluid was found in the lower pelvic cavity. Upon carefully inspecting the relations of the ligatures, the cord, consisting of four strong silk threads twisted together, which was tied around the whole pedicle on the distal side of the other three ligatures, had escaped from its original position, and lay loosely over the point of the stump of the cervix uteri. Neither of the other ligatures could be detached without cutting away the tissues on the distal side of each, and yet there was evidence that the middle ligature had cut into the tissues of the cervix, and afforded a clue to the probable source of the hemorrhages in the division of this substance supplied with vessels. The ligatures each remained well knotted, and retained their hold securely upon the several parts, with the exceptions noted, dependent on the yielding of the substance of the cervix uteri.

That the profound prostration resulting from the hemorrhage led to the subsequent result of decomposition, peritonitis, and in the end to septicæmia, cannot be doubted. Whether a timely recourse to a second ligature could have availed to avert the fatal result is so problematical that perhaps no operation would be warranted in opening up the abdominal cavity under the circumstances presented in this case after the hemorrhage was discovered. I am more thoroughly convinced, by this case, of the necessity of some measure that may adequately compress without lacerating the tissues of the pedicle, and the plan proposed, of tying the cervix firmly around a tube within its canal, offers advantages which no other process is likely to effect so satisfactorily.

These notes, made immediately after the several observations of the patient, are presented as a faithful delineation of the progress and termination of the case.

A review seems requisite, of the circumstances connected with the general condition of this patient, the freedom from adhesion or other complications on the part of the tumor, the immediate apparent successful termination of the operation, and the subsequent vital depression coming on with hemorrhage.

If there was an error committed in the mode of ligating the pedicle and in the departure from the usage of most operators by transfixing the cervix with a double ligature which is knotted upon either side, it would still appear that the division of the tissues into three segments instead of two should not, *cæteris paribus*, have predisposed to hemorrhage. If there had been only two loops, and either of them had been drawn so tightly as to press unduly upon the one or the other division of tissues, and thus cut through its texture, the same result must have ensued as that which occurred in this instance. We know that this is not an unusual accident in the over-tight ligature of the umbilical cord with a fine round silk thread, and hence a number of threads are most frequently employed together for securing it, or a soft narrow tape is even preferred for the ligation, to obviate the liability of cutting through the delicate texture of the umbilical cord. Each of the three ligatures employed in the three several loops for the respective segments, consisted of two distinct large threads of suture silk, while that around the whole pedicle contained four such threads, so that the tendency of a single cord to cut the tissues was not overlooked.

Yet the desire to secure effectually against the shrinkage of the mass included in those three separate loops, led to closing them too tightly, and even if the outside large loops of four strands had held firmly at the outset it could not have availed against the hemorrhage resulting from cutting of a vessel within this line and upon the cardiac side of this constriction. Although the tightening was done by the hand of the operator, my own finger was placed upon the first knot to secure it until the second knot was made in each loop, and neither I nor any one of my colleagues present thought for a moment that either of the loops were drawn too close. The one upon the right side of the cervix was examined by Dr. Pereira Lima, and supposed to be too slack, but a special examination satisfied me that it was sufficiently tight, and the inspection of the loops at their removal in the autopsy convinced me of this fact. If either ligature had been so slack after the shrinking of the tissues as to have admitted of the escape of some blood, it is not at all probable that the loop beyond of four strands yielded so easily as to have allowed so much blood to escape as was discharged within less than an hour after they were applied. The most rational inference, therefore, is, that the laceration or cutting of the cervix by the closely drawn ligature of two strands of silk was the occasion of the sudden and profuse flow of blood. It behooves us, therefore, to profit by this sad experience, and use in the future the flat tape ligature or a larger number of strands in the cord.

But for the fact that an opening was left at the lower angle of the incision, this patient would perhaps have died without discovery of the hemorrhage, as the whole train of nervous prostra-

tion and circulatory depression met a ready explanation from the supposed shock which is so prone to be manifested in this class of operations. Had the pedicle been secured outside with a clamp, it is very evident that such a result would not have ensued, and it must be allowed that the case was a favorable one for such appliance, as there could have been no difficulty in bringing the pedicle to the surface. But, whatever may be the security against hemorrhage offered by the clamp, it presents counterbalancing troubles that it is very desirable to avoid, and so soon as a like security against hemorrhage can be guaranteed by some other process, this most bungling device is destined to be banished from abdominal surgery by all gynecologists.

With the flat ligature and the intra-cervical tube, it is believed that all difficulty on this score can be obviated, and if this most desirable end can be attained consistently with perfect drainage and diminished risk of peritonitis and septicæmia, it must be allowed that this modification in hysterotomy is quite an important element of progress in abdominal surgery, and should be adopted by surgeons.

A careful consideration of the details presented, as to the construction and application of the intra-cervical and intra-vaginal tubes, with the special mode of ligation of the pedicles around them, is urgently recommended.

MEDICAL MISSIONS IN HEATHEN LANDS.

BY. M. P. BARKER, M.D.,
Of New Castle, Pa.

Before proceeding to a discussion of the principal topic embraced in my theme, viz., Medical Missionary Work, it would not be improper to make a diagnosis of our case, or, in other words, to review briefly the condition of the science and the art of medicine and surgery, in the lands called heathen.

In the most of these countries the status of the healing art, prior to the advent of Medical Missionaries, was much the same as it had been for thousands of years, the reverence of the people for their ancestors forbidding them to make any change. They worship the same gods, bow at the same shrines, make the same obsequious salaams, cultivate the soil in the same way, resisting any innovation upon the traditions and practices of their fathers.

In nearly all heathen countries disease is supposed to be of supernatural origin, sent upon them by their gods, or by the spirits of their departed ancestors. A recent writer from Ningpo, China, referring to this "one article of faith, common to all sects," says that it "leads to no kindliness or respect from sons to their living parents, but to a slavish dread of the dead, whose power to avenge any slight or neglect is so firmly believed in that no amount of pains and expense is spared to propitiate them." This belief, inculcated by Confucius and taught by the priests, has become so deeply rooted, that in order to protect themselves "from the inroads of hosts of spirits who are supposed to crowd in, many families are often permanently impoverished by the drain to which they are thus subjected." The same writer states that he had heard a calculation by one entitled to know, that "thirty million dollars are annually expended in China, at the three great festivals, in honor of the dead."

A belief in the existence of "disease spirits" is common, not only in heathen lands, but also among the aborigines of our own country, as well as among the untutored in Mexico and South America; and the physician, magician, priest, or astrologer who can exorcise these "disease spirits" often receives divine honors. The pathway of the smallpox spirit is, by many, supposed to be obstructed by thorns and bushes thrown in its way, or by digging trenches across its track, or by scattering stinking oils around their dwellings. Charms and amulets are worn suspended around the neck, containing a word, as "abracadabra," for instance, to keep away "disease spirits." The deafening noise of gongs and fire-crackers are also resorted to for the same purpose.

In China, Lecompte states that four thousand years ago Hoang Ti composed the code by which their physicians are guided to the present day. They have no knowledge of anatomy and physiology, in consequence of their superstitions preventing them from dissecting the human body. The nature of disease and the action of remedies are practically unknown. In obstetrics, the most absurd practices prevail. Dr. J. G. Kerr, of Canton, says: "I have been called to remove an unborn head, when the body had been torn away. I have seen barbarous mutilation of the mother, and the skull of the unborn child broken with rude instruments, in vain attempts to extract it. On several occasions I have seen the sacrifice of both mother and child, when a simple forceps operation would have saved one or both. These are specimens of cases that must be of frequent occurrence in that vast population. The belief is prevalent that the fœtus is

an active agent in its own birth, and I have seen a healthy woman allowed to die, while the midwife and friends were entreating the child to come away, after all uterine power was exhausted by protracted labor."

Their knowledge of sanitary laws is limited. The streets in their cities are narrow, crowded and filthy, with no drainage and no removal of filth, except by the agriculturist; no isolation of contagious diseases; no hospitals, insane asylyms or almshouses for the poor, and in case of war, no surgeons for either army or navy.

China is a vast sepulchre, her tombs containing millions of her population swept into untimely graves for want of knowledge of sanitary laws and a scientific knowledge of medicine.

The same superstitious ideas with reference to the origin of disease has existed in Egypt for thousands of years. The deity Isis was believed to possess a large amount of medical skill, and many diseases were attributed to her anger. Another of their medical divinities was Taaut. After the discovery of the manufacture of paper from the stalk of the papyrus, they collected the knowledge of Taaut in a book entitled "*Embre*, or *Scientia Casualitus*," to which the physicians were compelled to scrupulously adhere. If they did not they were punished with death, no matter what the issue of the disorder. Like other semi-civilized or barbarous peoples, they had no knowledge of anatomy or physiology, being afraid to dissect a human body for fear of incurring the anger of their gods; a very limited exception would have to be taken to this statement, as the *Paraschites*, or embalmers, removed the brains through the nostrils, and opened the abdomen to remove the contents. Egypt at the present time is becoming so rapidly Europeanized that many of their superstitions are giving way to the rapid advance of scientific knowledge. Rev. David Strang, who spent eleven years as a missionary in Egypt, and who "dabbled some in medicine," in a recent letter to the writer, says, "In Syria and Egypt medical men and religious advisers are to a considerable extent permitted to enter female apartments that are barred to all other men not members of the household. But even in these countries there are many households where a medical man would not be admitted." In the whole of the Turkish dominions woman is degraded and downtrodden. The heavy black veils and the seclusion still exist and will continue to exist until there is a much higher type of civilization. It seems marvelous that the Egyptians, who boast of their great antiquity, their civilization, their long line of Pharaohs, their pyramids and temples, their sarcophagi and magnificent tombs, their mummies and their schools of philosophy, should have remained in such profound depths of ignorance and superstition in the healing art. But the people are like the idols whom they worship; they have eyes but see not, ears but hear not.

In India the greatest obstacle to improvement in medical knowledge, and which has kept the people enthralled in ignorance for thousands of years, is caste.

The Brahmins comprise the savans and physicians, their knowledge being derived from their Vedas. But caste prevented them from dissecting the human body, and consequently they had no foundation upon which to rear a sound, rational, scientific structure of medical knowledge.

If a Brahmin should touch a dead body, even though it be his own father, it could not be atoned for, except by many days of purification and much alms. If a Pariah should touch a Brahmin, the latter would be considered justifiable in killing him.

The Zenana caste cuts off access by the male physician to the wives and daughters of what is called the High Caste portions of society. It is the testimony of missionary ladies, that when sick they are neglected and permitted to die, rather than call a male physician. Weaker than man, physically, she is not only compelled to suffer the diseases common to both sexes, but she has also to bear the pangs of maternity without the aid of scientific skill or the bliss of an anodyne to relieve her sufferings. Behind those thick veils and those barred doors there has been an amount of suffering which the power of language could not describe.

During the present century, through the efforts of missionaries and the fostering care and aid of the English government, a very great change has been effected. Caste is not dead, but it is gradually losing its hold, in consequence of the dissemination of medical knowledge.

I do not propose to enter into further detail of the condition of medical knowledge in other heathen or semi-civilized countries; the ones already mentioned being typical of the rest. Suffice it to say that they are all fettered by the same chains of ignorance and superstition, all under the influence of their gods; all destitute of a knowledge of anatomy and physiology, and in many cases ignoring the profession altogether.

Among the western nations medical knowledge has reached a high degree of perfection.

The nineteenth century will be renowned in history for its research and progress in every department of the healing art. But its renown will be greatly enhanced in consequence of the efforts made to propagate this knowledge in heathen lands, which has proved to be no longer an experiment, but a decided success. By whom, how, and with what success, will be reserved for future articles.

(To be Continued.)

Hospital Reports.

MEDICO-CHIRURGICAL COLLEGE.

SERVICE OF F. LE SIEURE WEIR, M.D.

Clinical Professor of Dermatology.

Reported by Dr. H. B. Nightingale, Chief of Clinic.

Acne.

Case 1.—The young man before you to-day is an Englishman by birth, 21 years of age and unmarried. His occupation is that of a laborer. About 6 years ago his face, which had previously been clear of any eruption, showed here and there small, red pimples, some of which pustulated, others again remaining stationary for a few days, and then disappearing. From being a few in number they gradually increased until he was 18 years old, at which time he began to shave. Since then the condition now observable has been present, new crops appearing to take the place of those which had run their course. His appetite has always been good, in fact, too good. Bowels inclined to constipation. He sleeps well, has never had gonorrhœa or syphilis. A close inspection of the face shows this eruption to consist of small, elevated points or pimples, which are solid, and have a feel not unlike the pustules of smallpox, vivid red in color, and causing some little sense of discomfort by the tension of the epidermis, commencing at or shortly after puberty, with no specific history, an evidently deranged digestion and habitual constipation.

These give us all that is necessary to know about the disease. Masturbation is a very frequent cause of this affection, or if not a direct cause, largely assists in keeping up the irritation. There is no history of such practice in this case.

He will be ordered 5 gr. doses of lactopeptine 3 times a day, to be followed by a bitter tonic. Also the following:—

℞. Ext. cascara sagrada, fld., f℥j.

Sig.—Gtt. x, in sweetened water, before each meal and at bedtime.

This will have the effect of producing a free evacuation daily, and if he will continue its use for some time his constipation will yield permanently. I know of no drug which relieves habitual constipation so effectually as the cascara sagrada. Locally he shall have a soothing ointment of oxide of zinc and cosmoline, with a few drops of carbolic acid. The local treatment is secondary, for upon the relief of the dyspepsia and constipation a marked change will be observed. He will be directed to let the beard grow, thereby removing one potent cause of irritation.

Erythema Simplex.

Case 2.—A. M., 30 years, Irish, and employed as a cook in one of our hotels. She is constantly bending over a hot range, owing to her occupation, and some weeks ago noticed that the redness of the face, which had previously disappeared after a time, began to remain longer. Presently it became so bad as not to leave at all, and gave rise, in addition, to burning, smarting, and more or less itching. The redness, as you have seen, involves pretty much the whole face, not, however, producing a uniform discoloration. The redness is in patches, which coalesce with each other, leaving a ragged margin. By passing the finger over the surface the patches are found to be very slightly raised, and the redness disappears, returning again instantly upon removing the pressure. It is a case of erythema simplex, or superficial inflammation of the skin, from external irritation. In the way of treatment, removal of the exciting cause is the primary object. In all idiopathic cases it is the one thing to do. If we can get the patient's coöperation in this we will order her a simple oxide of zinc ointment, with possibly a few drops of carbolic acid.

Urticaria.

Case 3.—H. J., 18 years. Here is a young lady who comes to us suffering from "the hives." Here, upon the forearms, you see these large, red blotches, each with a pale or whitish centre, no regularity as to distribution, but lying close together on some parts of the limb, while upon the hand, considerably removed from the others, are more patches. They are quite prominent, and give rise to a most exasperating sensation of burning and itching. Even now you see she cannot refrain from scratching the parts. Both arms and hands, and the face as well as neck are involved. Doubtless the body and lower limbs share the affection in turn. There is never any difficulty in recognizing the disease, the wheals are so characteristic. In no other disease do we find wheals appearing suddenly, and, after remaining a varying time disappearing as rapidly and mysteriously as they came. It is a most common difficulty, and the diagnosis is easily made out. But *what causes* it is not always so easy to ascertain. A case of urticaria or nettle rash in which the exciting cause is unknown is one of the most stubborn and unsatisfactory of all, and the doctor to whose lot it falls is apt to become disgusted with the study of dermatology. The exciting causes of urticaria are divisible into three heads: local irritants, a polluted circulation, and reflex irritation. Without going deeper into the subject, let me say that the first two causes are easily disposed of, and it now remains to be seen *how* reflex irritation is responsible. The patient yesterday morning indulged in fish for breakfast, and in the course of the afternoon felt a burning and smarting upon various parts of the body. It was not severe, however, till night, when she got warm in bed, at which time it became almost unbearable. Once or twice before fish has had the same effect

upon her, but not for several years. She is of a nervous temperament, evidently, and this fact renders it all the more easy for the disease to manifest itself. My assistant tells me that just before coming into the room there was no sign of wheals, yet upon her entrance, I was able to show you some very fine specimens of them. The disease is, I feel convinced, a neurosis, not alone in the case before us, but demonstrably so in every case. The divisions I gave you a few moments ago are made for the sake of convenience only, and if the first two so-called heads be eliminated I think that reflex action can be clearly shown to be the cause of the cutaneous phenomena in every case.

The treatment in the present case shall consist of three compound cathartic pills. Considerable constipation is present, and as no stool has been had since the eating of the fish, it will have the effect of removing the remnants of it and clearing out the alimentary canal. Locally, a lotion, as follows:—

℞. Ammoniæ carbonatis, ℥ ss
Plumbi acetatis, ℥ j
Glycerinæ, f℥ j
Aquæ rosæ, f℥ v. M.

Sig.—Use as a wash, several times daily.

Without doubt our patient will obtain relief by these measures.

Eczema Aurium.

Case 4.—Willie S., aged two years. The child before you is brought here on account of an eruption which made its appearance in the neighborhood of the ears about two and a half months ago. As you see, not only the cleft behind them, but also the auricles themselves, are involved. The inflammation, however, does not seem to have extended into the auditory canal to any appreciable extent. A hot, red, tense and swollen surface, with a thin, serous fluid constantly bathing the parts; numerous small vesicles, in varying stages of development; a feverish state of the body, and constant fretting; a strumous diathesis, poor appetite and costiveness, all of which are present, mark the case unmistakably as one of eczema. The suffix of aurium designates the seat, not that it differs from the same variety in any other portion of the body.

This state of affairs has been going on for a period of two or three months, the symptoms becoming gradually worse, until life has become a burden to him, young as he is. If allowed to go on the symptoms would probably not change noticeably, except the discharge, which would become purulent. Indeed, it is so to a slight extent already. The only wonder is that such has not been the case long ere this. Being a catarrhal inflammation essentially, it is more apt to assert itself in an intractable form when occurring in lymphatic children.

We must try to relieve the little fellow, and to this end will advise the following to be applied to the parts two or three times daily:—

℞. Zinci oxidi,
Zinci carbonatis, āā ℥ ij
Glycerinæ, f℥ iij
Aquæ rosæ, q. s. ad f℥ iv. M.

Sig.—Shake well before using.

The surface is to be dried by *pressing* gently with a piece of soft muslin. Never *wipe* an inflammation. This lotion should leave a fine powder upon the surface, and by the protection which it affords the parts the air is excluded. He shall have also:—

℞. Potassæ chloratis, ℥ j.
Fiat. chart. No. xx.

Sig.—A powder to be dissolved in water and taken thrice daily.

Were the patient older we could administer cod-liver oil with advantage, but young children do not, in my opinion, assimilate it so well, and, moreover, will not take it. The chlorate of potassa here answers an admirable purpose as an alterative, and in the present case will, I feel sure, fulfill all the indications of the oil. Some time will be required to effect a cure, but I think we may safely predict success in the end. The mother will be directed to bring him back in a week, at which time he will be shown you, and any necessary changes in the treatment effected.

UNIVERSITY HOSPITAL.

CLINIC OF JOHN ASHHURST, JR., M.D.,
Professor of Clinical Surgery in the University of Pennsylvania.
Reported by Louis J. Lautenbach, M.D.

Re-excision of the Knee, Nine Years after Previous Operation.

Case 1.—The girl whom I will bring before you to-day was a patient of mine nine years ago, at the Episcopal Hospital, when I performed, on her right leg, the operation of excision of the knee. She remained in the hospital for over a year after the operation, and left with a perfectly straight limb, and with, apparently, firm, bony union. Two years after she left the hospital, however, the leg again began to contract, the deformity steadily increasing until three years ago, when she was obliged to resume a crutch, which she has used ever since.

At the time of the operation she was eight years old, so that she is now seventeen. She now finds it necessary to do something for herself, and, as her contracted knee prevents her from obtaining employment, she comes back to know if her leg can be again straightened. Had she returned on the first appearance of re-contraction it would have been easier to effect the object by the use of suitable splints and bandages. I succeeded, some years ago, in a case of re contraction of the knee-joint excision, in restoring the limb, by applying a padded posterior splint and an india-rubber bandage, so as to straighten the limb by means of elastic pressure.

A point which is well illustrated by this case is the occasional long continuance of the soft condition of the callus in children. The same thing is seen in cases of fracture; union occurs very quickly, and the bone appears firm, but re-fracture may occur at the same point, owing to the soft or cartilaginous state of the callus, many weeks or even months subsequently. In this case the callus must have remained soft for a very long time, as the limb appears to have continued straight for three years, and flexion not to have begun until the end of that time.

Bony union is now complete, and under the

circumstances all that can be done is to straighten the leg by another operation. This will consist in exposing the angle of the limb, and removing with the saw a wedge shaped portion of bone. As a necessary consequence of this operation, the limb, already shortened by the previous excision, will be still further reduced in length, but will be straight and useful.

This operation is not, I think, as serious as that of excision of the joint, and will not, probably, be followed by as much constitutional disturbance. It is still, however, a grave operation, making a compound fracture, which will, of course, be attended by the ordinary risks of that injury.

The saw which is so useful in ordinary operations of excision, Butcher's saw, is not so well adapted to an operation of this kind, and I will use instead the ordinary amputating saw. The splint to be used after the operation is the simple bracketed wire splint, with a movable foot-piece, which I employ for excision of the knee. It allows the leg to be firmly fixed above and below the wound, while the wound itself is left open, and can be dressed every day without disturbing the rest of the limb.

Examining the limb, we find the angle to be rather less than a right angle, it being not more than 80°. We see here the cicatrices of the old operation, which I will avoid in cutting down to the bone.

In overcoming the deformity here, we must be careful in regard to the popliteal artery and vein, which may possibly be shortened in connection with the contraction of the joint, under which circumstances they might be ruptured in a forcible effort to straighten the limb. The hamstring tendons may be subcutaneously divided, if their contraction interferes with the restoration of the part to the straight position.

I will not use the Esmarch bandage, but will tie the vessels as they are cut. I will make an incision a little above the cicatrix, down to the bone, and will turn flaps upward and downward, so as to expose the prominent part of the bone. Now, with the saw, I cut out a wedge-shaped piece, including the base of the femoral condyles and the upper part of the tibia. I take care to avoid opening the medullary cavity of the femur, as its implication in the operation would entail additional risk. If the parts do not come readily together when the wedge is removed, additional slices can be taken away from either side. A hole is next drilled through the anterior edge of each bone, and a strong silver wire introduced and twisted, so as to fix the bones together. The use of a bone suture is a useful precaution, though not absolutely necessary.

The bracketed wire splint is now well padded with oakum and adjusted to the limb, the foot being secured to the foot-board by broad, adhesive strips and bandages, and the limb above and below the knee also fixed to the splint by the same means; after which the wound is dressed with oiled lint, protected with waxed paper or oiled silk; this again with a pad of oakum, and the whole surrounded with turns of a roller.

Scirrhus of Breast—Removal.

Case 2.—This woman, 31 years of age, has a tumor of the left breast. It is most prominent above and to the outer side of the nipple, but involves the whole gland. The glands of the axilla are also enlarged and infiltrated. The skin is adherent to the tumor, which presents the appearance of a scirrhus or hard cancer, an affection which is rarely met with at so early an age.

We will remove here the entire breast, as well as the infiltrated axillary glands. Two curved incisions are made to include the adherent portions of skin, and from the centre of the wound thus made a V-shaped cut is carried downward so as to embrace the nipple. The flaps thus formed are laid backward, fully exposing the tumor, which is then readily removed, principally by tearing. The axilla is next explored, and all the glands that can be reached are enucleated with the finger and handle of the scalpel. The wound is then painted over with a fifteen-grain solution of chloride of zinc; any vessels that bleed should be tied as they are divided, and the edges brought together with sutures and supported with adhesive plaster. Drainage tubes should be arranged so as to allow the escape of fluids from the deep parts of the wound. A simple dressing of oiled lint is applied, covered with oiled silk and kept in position with a pad of oakum or cotton and a roller bandage.

Congestion of the lungs is a complication to be guarded against after breast excisions, being sometimes caused by the exposure of the chest necessarily incident to the operation. To avoid the risks of heart-clot—the pathological condition found in cases of so-called secondary shock—we will give both this patient and the one last operated upon carbonate of ammonium in five-grain doses, every two hours, until to-morrow.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, Nov. 23d, 1882. The President, Dr. Jas. Tyson, in the chair.

Great Hypertrophy of the Heart, due to Severe Valvular Lesions.

Presented by Dr. M. O'Hara.

J. H., male, æt. 30 years, laborer, contracted syphilis when 18 years of age. Health good until within past three years, when he began to suffer from pains in the left breast, palpitation of the heart, and slight dyspnœa, after violent exertion. Gradually becoming worse and unable to work, he was admitted into St. Mary's Hospital in June, 1882. He then complained of great pain over the upper part of the sternum, in the left arm and shoulder. He lost considerably in weight, his appetite was poor, and albumen was present in small proportion in his urine, although casts were absent. He had marked dyspnœa on admission, which increased rapidly until sleep could only be obtained in the upright position. There was no evidence of pulmonary trouble. With the forearms flexed to a right angle, the brachial arteries became prominent at each impulse of the heart; the pulsation of the carotids was wavy and prolonged; the

temporals were tortuous and visibly pulsated; no retinal arterial pulsation was seen. Retinal venous pulse was marked, but no visible venous pulsation was detected elsewhere. The left præcordial region was specially prominent. The apex beat was most distinct in the sixth and seventh interspaces on a perpendicular line running mid-way between the left nipple and anterior border of the left axilla. The heart's impulse was usually forcible and diffused, but at times it became weakened and wavy. In the second left intercostal space a systolic impulse was observed. The pulse varied from 80 to 120 per minute, struck the finger with considerable force, but at once lost most of its volume. All these phenomena were exaggerated by raising the hands above the head. The radial pulses were unequal, but the brachial arteries presented no differences. No hepatic pulsation was felt. The cardiac area of complete dullness was nearly twice its normal size, the increase being downward and to the left. Over the second right costo-sternal articulation, the closure of the aortic valves was distinctly heard, and with this a slight diastolic murmur. A systolic murmur was also heard over the same spot. The systolic murmur was nearly lost in the carotid and sub-clavian arteries, but the diastolic one remained distinct. On a line with the second costal cartilage, over the sternum, and to the left of this bone, the diastolic and systolic basic murmurs were most intense. Over the cartilage of the left fourth rib, the murmurs heard at the base of the heart were less distinct, or were obscured by the development of other murmurs. In this situation, a short, sharp, presystolic murmur, apparently prolonged into a systolic one, was detected. At the apex, and just above it, the systolic murmur became intensified, its blowing character aiding in differentiating it from the short, harsh murmurs which immediately preceded it. From the fourth to the seventh rib, and from the sternum to a point about five or six inches to the left, a diastolic murmur of considerable intensity was heard. The character of the diastolic murmur over this area was different from that presented by the second sound murmur at the base of the heart, and its intensity was much greater. Posteriorly at the lower angle of the left scapula, a blowing systolic murmur, entirely deprived of its harsh presystolic complication, was heard. Dr. Eskridge thought the physical signs justified him in venturing the diagnosis of constriction and regurgitation at the mitral orifice, a rare form of mitral regurgitation, produced by the inability of one of the aortic semi-lunar valves to close while the others acted properly; great hypertrophic dilatation of the left ventricle, and to a less extent of the left auricle; and aneurismal dilatation of one of the great vessels, probably of the pulmonary artery near its origin from the heart. The patient rapidly sank. Œdema of the feet, lower portion of the trunk and lower extremities, with hydrops pericardii pleuræ and of the peritoneum, developed. He died, exhausted, in August, nearly two months after admission to the hospital.

Sectio cadaveris.—Brain: Some venous congestion of the pia mater. The brain substance and the ganglia nearly normal in appearance. Thorax: The pericardium was nearly filled with serum. The only evidences of inflammation were a few patches of recent lymph at the left anterior upper portion of the sac. The heart weighed eighteen ounces, the increased weight being chiefly due to eccentric hypertrophy of the left auricle and ventricle. The right ventricle was dilated, with slightly thickened walls. The aortic valves were insufficient and thickened. The posterior leaflet was normal in shape, but the others curled upon themselves on the aortic side of the orifice. The stenosis was slight. The mitral orifice was button hole shaped and the valves failed to close, on account of calcareous deposits in their tissues, this degeneration also involving the inner surface of the left side of the auricle contiguous to the valves. The auricular surface of the valves was fairly smooth, but in the ventricle just beyond the valves, and attached to them, hung a bony substance about one-eighth of an inch in diameter. The left auricular appendix was much hypertrophied. The valves at the tricuspid and pulmonary orifices were normal. The pulmonary artery was considerably dilated. The pleural cavities contained several ounces of serum. There were old adhesions at the apex of the right lung posteriorly, and at the same spot of the left lung anteriorly. Several patches of recent lymph were also found at the lower part of the left pleural cavity. Abdomen: The peritoneal cavity contained considerable serum, and its veins were engorged. The liver was enlarged, with distended veins. The kidneys were highly congested. The spleen was double its normal size and softened.

Abscess of the Liver Following Arrested Menstrual Discharge, from Exposure to Cold; Pyæmic Abscesses of the Lungs and Spleen; Perforation of the Bowel; Severe Heart Complications; Death During the Seventh Week.

Presented by Dr. J. T. Eskridge.

M. D., aged 28 years, was a factory girl whose father and two sisters had died from heart disease. She had had two attacks of inflammatory rheumatism but had never complained of heart trouble. Her fatal illness began at night, by arrested menstrual flow, and severe cramping abdominal pains, coming on after exposure to cold during the previous afternoon. Fever and pain in the right lower side of the abdomen continued for three days, when she was able to work again for about a week. Jaundice began early, was well marked during the first three weeks, was slight afterward, but lasted until her death. Her symptoms three weeks after the beginning of the attack, when admitted into St. Mary's Hospital, in Dr. Hickman's wards, were, great prostration, emaciation, loss of appetite, pain in the right inguinal and lumbar regions, and irregularly recurring chilly sensations. Two weeks later, when first seen by Dr. Eskridge, the liver dullness extended nearly to the anterior superior process of the ilium, and the normal tympanitic note of the right inguinal region of the abdomen was replaced by one bordering on dullness. The tenderness was so great that neither fluctuation nor a tumor could be detected, if such existed.

Great tympany soon developed and obscured the physical signs. A pyæmic condition, from which the patient perished in about two weeks, set in, attended by chills, fever, sweating, low temperature, and diarrhœa. A few days before death she passed considerable pus by the bowels. The surface temperature, taken over the chest and abdomen, showed the latter to be about two degrees warmer than the former, but all parts of the abdomen were nearly the same temperature. Stenosis of the aortic and mitral orifices, with insufficiency of the valves of the latter, and a dilated hypertrophy of the left auricle and ventricle, were recognized during life. The post-mortem examination revealed the diagnosed lesions of the heart, and demonstrated the possibility of visible left auricular pulsation; the liver weighed eighty ounces (the right lobe being alone enlarged), and contained a large abscess, surrounded by several smaller ones, with which it was connected. The cæcum and its appendix were surrounded by about six ounces of pus, the latter being circumscribed by adhesions. Two openings were found in the black and gangrenous cæcum, one where its appendix had sloughed off, the other due to perforation of the bowel by the pus. The portion of the liver external to the hepatic abscess was firmly adherent to the abdominal wall, and from this point (about two inches above the crest of the ilium) the pus had burrowed its way and formed a sinus leading to the right inguinal region, under Poupart's ligament. A direct communication between the liver abscess and the accumulation of pus surrounding the cæcum was seen.

Dr. Eskridge thought that the demonstration of the possibility of visible left auricular pulsation in the second left intercostal space, and of the occurrence of a functional murmur in the pulmonary artery, without dilatation of that vessel, was worthy of notice at present, as Dr. Broadbent had so recently advocated views almost diametrically opposite. Dr. Eskridge considered mitral stenosis of not infrequent occurrence, and said, with care, the mitral presystolic murmur was not usually difficult to detect. The four physicians, including himself, present at the autopsy, then thought that the hepatic abscess was secondary to the inflammation and suppuration around the appendix and cæcum, but he, after carefully analyzing the clinical evidence and pathological lesions in favor of each condition, was satisfied that the case began as one of primary abscess of the liver, following exposure to cold while the patient was menstruating.

The discussion on both these preceding specimens, which presented somewhat similar heart lesions, was now opened by Dr. J. B. Wilson, who said that there was one point of special clinical interest in Dr. Eskridge's case, viz., the chronology of the lesions. He thought that the extensive multiple abscesses of the liver and lungs were secondary to the abscess around the caput coli. In some cases the determination of the primary source of the emboli was difficult, but in this case it was perfectly clear.

Dr. Bruen said that he would like to go on record among those who had observed auricular pulsation in cases of mitral obstruction, in which the stenosis was extreme.

Dr. Nancrede remarked that in his experience flexion of the thigh or the abdomen was an almost invariable early symptom in cases of perityphlitis, from which he would infer that as this thigh flexion did not occur in Dr. Eskridge's case until within ten days of the fatal termination of the case, the peri-cæcal abscess was secondary to that in the liver.

Dr. Tyson said that he had been much impressed with the marked increase of the surface, temperature in the neighborhood of the abdominal abscesses as compared with the general body temperature; as to the chronology of the various affections, he was inclined to believe that Dr. Wilson was correct.

Dr. Eskridge said, in reply to Dr. Wilson, that he could appreciate how the perityphlitis might be mistaken for the primary trouble, and the hepatic suppuration for the secondary; such a mistake (for he felt certain that the abscess of the liver was the primary affection), was made by all, including himself, who were present at the post-mortem examination. The pathological and clinical facts in favor of primary hepatic abscess were given at some length in his remarks in connection with the presentation of the specimens. In brief, the clinical features were as follows: Deep and early jaundice following exposure to cold, pain in the right side of the abdomen, attended by fever and gastric irritability of a few days' duration; an intermission of a week, during which she was able to work, followed, after which gradually increasing weakness with dull abdominal pain, attended by loss of flesh and appetite, confined her to bed; ten days before death the development of intense tympany associated with flexion of the right thigh upon the abdomen. The hepatic suppuration was confined to the right side of the right lobe, all the smaller abscesses directly communicating with the large one, and the left lobe of the liver being apparently healthy.

Tongue and Larynx from a Case of Elephantiasis Græcorium.

Presented by Dr. A. C. W. Beecher.

The case from which these specimens were removed was reported in the *Photographic Review of Medicine and Surgery*, No. 6, Vol. 1, Aug., 1871.

M., aged 26 years, born in Cuba, of Spanish parents, married. His father was living when the patient died, in 1872; the mother died when he was an infant. He was wet-nursed by a colored house-servant, who was unmarried, but had had several children by different individuals. She was healthy as far as known, with the exception of sores upon her feet. He had none of the diseases of early life except measles and mumps. His health was good up to 15 years of age, when superficial, yellowish-pink spots appeared upon his body, accompanied by neither pain nor itching. They remained about one year, and disappeared during a voyage to Spain. While there he was attacked with neuralgia of the little fingers, extending along the course of the ulnar nerve to the elbow, which was relieved, and he returned to the West Indies. Six months after his return he experienced a second attack, which lasted for one month. In 1862 he came to this

country to study, and, after one year, became the subject of repeated catarrhs, chiefly affecting the throat. Itching of both forearms and legs soon after developed. In 1866 œdema of the hands and feet, which did not extend beyond the wrist or ankle, set in, producing a sensation of stiffness of the fingers and toes. Blebs then suddenly appeared in varying size upon the dorsum of the hands and fingers, extending over the whole length of the latter. At times a sharp pain in the hands and fingers, arousing him from sleep, would herald one of these bullous attacks. The bullæ contained a whitish, opaque fluid, and, when burst, were succeeded by dark-brown scabs, transversely cracked and fissured over the joints. Under these crusts were excavated ulcers. The finger tips and the ends of the toes presented similar ulcers, over which the nails grew, and these latter, being brittle, broke off when long. Next, frequent hemorrhages from the nose, coming on while laughing or in mental or physical excitement, were noted. The nose became tender, was much swollen, and discharged moderately offensive pus, and the bridge of the nose began to sink, gradually assuming its present appearance [a photograph was here shown]. A year after the hands were attacked the face became similarly affected, the ulcers, on healing, leaving distinct cicatrices. The eruption never entirely ceased, new bullæ and ulcers forming while others healed. There was marked emaciation. The hair was absent in many spots on the body, and was everywhere scanty, and the skin was of a dusky hue. The muscles of the arms were much wasted, and the skin presented small white cicatrices. Over both patella and olecranon processes, large, hard, firm, reddish nodules were seen. The hands were much deformed, with wasted, contracted fingers, having numerous small, hard tubercles scattered beneath the skin of the dorsal surface of the hands. Numerous ulcers, mostly covered with irregular black scabs, cover the back of the fingers. A markedly varicose condition of the veins near the wrist was observed. The hair of the head was normal in quantity but was hard and harsh, while there was total loss of eyelashes and eyebrows, and the beard was scanty. There was a large, hard tubercle over one frontal bone, near which was an old ulcer. The nose was much sunken; there was an ulcer over the right zygoma, covered by a black, rupial-like scab; the face was marked with scars, and the ears were likewise deformed with traces of numerous cicatrices. Many of the teeth were decayed and broken off close to the gums. The tongue was much thickened with greatly enlarged papillæ. The velum palati was almost gone, from ulceration, and yellowish-white tubercles existed in the pillars of the fauces. The larynx was much contracted by thickening of its mucous membrane. The epiglottis was about twice its normal thickness and had several well marked tubercles upon it. The voice was merely impaired, weak, and had a peculiar husky sound. There were deep sloughing ulcers over each tendo-achillis. Tactile sense was very much impaired, as on the dorsum of the hands, where the sense of touch was almost absent, and what was recognized was referred to some point in the neighborhood of the point of contact. The sense of pain was almost entirely absent in the hands and forearms, becoming more marked as the body was approached; a pin passed through the pulp of the middle finger gave absolutely no pain. The difference between very hot water and that of an ordinary temperature was readily perceived, moreover, there was general increased cutaneous sensibility to temperature changes. Taste and smell somewhat impaired. Very slight anæsthesia of the trunk exists. Sight was good, although prolonged use of the eyes was painful. The general health of the patient was fair. There seemed to be no trace of venereal disease. Sexual power was absent. Frequent neuralgic pains of the legs and arms were complained of. The atrophy of the hands, feet, fingers and toes was appreciable from month to month. The cornea next became ulcerated, the conjunctival surfaces became adherent, and almost total blindness ensued. Swallowing was almost impossible toward the last, owing to the pain produced by the throat ulcers, and because of imperfect closure of the rima glottidis fragments of food entered the larynx, producing violent and exhaustive coughing. Respiration was also so much impeded that he died Oct. 29th, 1872, partly from dyspnœa, partly from starvation. Up to the death he suffered intensely.

Autopsy.—Rigor mortis well marked. Great emaciation of the entire body noted. The surface of the tongue was fissured, the papillæ enlarged, with the remains of tubercles well marked toward its base. The epiglottis was curved on its long diameter, thickened and stiff, with its upper margin eroded by a large ulcer. A deep ulcer was situated in the mucous membrane, near the apex of the left greater cornua of the hyoid bone. Narrowing, from thickening of tissues, involved the trachea at its upper part, and produced such stenosis of the chink of the glottis, that an ordinary quill could not be passed between the vocal cords. Upon section of both ulnar nerves near the elbow, extensive degeneration was detected. This case was examined both by Dr. Duhring and Dr. R. M. Bertolet, the latter making a laryngoscopic examination, who both considered it to be of the mixed variety, viz., tubercular and anæsthetic leprosy. The case is interesting, both from its rarity and the possibility of other cases being brought here from California and New Brunswick, in both of which places it is not uncommon. Again, its resemblance to syphilis at first led me into error, although, said Dr. Beecher, I recognized something strange about the disease. The late Dr. Maury saw the case with me, and had no doubt of its syphilitic nature until Dr. Duhring's examination convinced him that it was really leprous. Erasmus Wilson says, "The resemblance to secondary syphilis is so striking that an error is certain, excepting on the part of those who have had an opportunity of seeing and observing leprosy."

Dr. Wilson asked whether the family history had been investigated. Dr. Beecher replied that he had carefully questioned all concerned, but had ascertained nothing special, except that when such cases occurred in wealthy families, the fact was always hushed up. Dr. Wilson said

that in this connection he would call the attention of the members to a very able article in the last issue of *Hay's Journal*, where the writer took the view that leprosy was contagious, maintaining that it should be investigated where it was of rare and recent occurrence. Dr. Wilson also referred to its occurrence among recent immigrants in certain of our northwestern States. Dr. Carl Seiler said that Dr. Beecher had asked him to examine the specimens of the larynx and tongue of the case of elephantiasis. The dorsum of the tongue was deeply furred, and the papillæ appeared enlarged. The epiglottis was thickened, very stiff, and rolled on its long axis, like a dry leaf. On its upper free margin was a crescented ulcer with raised edges, and numerous smaller roundish ulcers were scattered over the laryngeal surface of the epiglottis. Extensive ulceration of both ventricular bands and vocal cords existed, so that the opening of the ventricles was almost entirely occluded. The ulcers were symmetrical, and most marked toward the anterior insertion of the vocal cords. About one-quarter of an inch below the cords was a cicatricial band projecting from the sides of the subglottic cavity, and leaving an elliptical opening through which a crow quill could hardly be passed. Below this obstruction the mucous membrane of the subglottic cavity was studded with small round ulcers, while the trachea seemed healthy. No further lesions could be detected by the naked eye, although, doubtless, such had existed but had been obscured, owing to long preservation in alcohol. Dr. Seiler regretted the absence of the records of the laryngoscopic examinations made before the patient's death; still, the lesions seen in the speculum would explain the symptoms of dyspnœa, aphonia and dysphagia, and it was astonishing how the patient could have respired at all through the narrow opening left by the cicatricial tissue below the glottis. The chief interest, however, centered in the great similarity of the lesions in this unique case with those found in syphilis and lupus of the larynx. He had seen ulcerations in syphilitic laryngitis almost identical in shape and location with those seen in the specimen, and he remembered having seen two or three specimens of lupus of the larynx when in Vienna, which bore a strong resemblance to syphilis. Lupus and leprosy of the larynx could not be diagnosed from one another by laryngoscopic examination alone, but other signs and symptoms outside of the larynx had to aid in the diagnosis. Thus in a syphilitic laryngitis there were always sharply defined bands of a deep red color on the free margin of the velum palati. The lupus affections of the skin of some parts of the body always preceded, coexisted with, or shortly followed the manifestations of the disease in the larynx, while in leprosy the larynx was usually attacked later in the disease, when other portions of the body clearly showed marks of the pest.

Dr. Little remarked, that having conversed with Dr. F. H. Enders, who had seen a great many cases of leprosy in the Sandwich Islands, he had been interested to note that the eyelids were affected in the early stages, ectropion resulting, and the conjunctiva and cornea, or even the whole eyeball becoming involved. The affection of the eyelid is sometimes the first symptom, or occurs during the first or second year of the disease. The lids were involved in the case described, and the eyeball subsequently.

Dilatation and Atheroma of the Pulmonary Artery, with an Opening Through the Intraventricular Septum.

Presented by Dr. Bruen.

Examination of the Heart.—Left side: Slight ventricular hypertrophy; mitral valves somewhat thickened at the margins, with roughening of their auricular aspect; valves competent; the left auricle is normal, as is also the aorta and the aortic valves. Examination of the right is of most interest. Two of the semilunar leaflets of the mouth of the pulmonary artery are nearly destroyed by atheromatous changes, the third segment is much thickened and projects as a leaf-like fold, roughening the mouth of the pulmonary artery. This vessel is dilated to twice its normal size, forming really an aneurismal dilatation. The vessel walls are covered with a fringe of vegetations, of inflammatory origin, or due to atheromatous changes. The right auricle is very small and imperfectly developed, the bulk of its cavity being formed by the auricular appendix. The tricuspid valves are much thickened but are competent probably. Between the two ventricles is an orifice large enough to admit the forefinger. It is directly beneath one of the two tricuspid leaflets, and is lined with endocardium, and must have allowed a free interchange between the blood of the two ventricles. The walls of the right ventricle are thinned and its cavity somewhat dilated. Dr. Bruen said that this case was interesting, because perforation of the ventricle or septum is often congenital and dependent on obstruction of the orifice of the pulmonary artery, the perforation being due to the pressure of blood within the replete right ventricle. This pressure causes an arrest in the development of the ventricular septum. The pathology of the present case probably is as given above, but there was no pulmonary artery obstruction. A similar case is recorded in the *Medico-Chirurg. Trans.*, vol. xv., by Fletcher. (2). There was no cyanosis. Cyanosis is usually dependent on a deficiency of cardiac evolution, or else on retarded evolution of the pulmonary artery or aorta. As a consequence there is deficient cardiac power to carry on the circulation; or the pulmonary artery or the aorta are narrower than normal, so that in any of these conditions venous repletion results and cyanosis; mixture of the venous and arterial blood is not, then, a usual cause of cyanosis, although it may be a factor. Walsh says, "Grant that perforation of the ventricular septum coexists with constriction of the pulmonary orifice, and cyanosis seems to become a certainty." In our case there is an example of incomplete development of the ventricular septum and deficient development of the right auricle, without cyanosis. (3) Pulmonary artery disease is consistent with a fair amount of general health, and that compensation by the right heart may occur, just as in cases of aortic disease. (4). Descriptions of pulmonary artery disease call attention to bronchitis, pneumonia,

hydrothorax, as sequential states. In our case no such complications were present until just before death, when she finally succumbed to congestion of the lungs added to the cardiac state. (5). The aneurism of the pulmonary artery formed a pulsating tumor on the left side of the sternum, between the second and fourth ribs, extending outward from the border of the sternum and including an area covered by a trade dollar. (6). Over the tumor a post-diastolic and a presystolic, bruit-like murmur could be heard, at a point between the second and fourth ribs, while close to their junction with the sternum a hoarse systolic murmur could be heard. The bruit was localized, the heart systolic murmur was carried out into the entire arterial system.

Dr. Bruen then detailed at length the differential diagnosis of these murmurs. During life dilatation of the pulmonary artery, with mitral obstruction, had been the diagnosis. The patient was a woman, aged 24 years, a syphilitic, and was under observation from Nov., 1878, to July, 1882.

Dr. Eskridge had not had any difficulty in differentiating a presystolic from a diastolic murmur. He thought the leathery thickening of the mitral valves, in the specimen presented by Dr. Bruen, was sufficient to give rise to a mitral presystolic murmur. If we adopt the theory of Dr. Austin Flint, Sr., that a mitral presystolic murmur may occur in aortic regurgitation when the mitral valves are perfectly healthy, it seemed to him that there was no difficulty in accounting for the presystolic murmur, from the regurgitant blood from the pulmonary artery into the communicating right and left ventricles of this case, especially as thickening, loss of elasticity, and some rigidity of mitral valves existed. The chronometry of the pulsations that occurred in the left second intercostal space, he thought could have been obtained by adopting Sansom's modification of Balfour's method of comparing the time of the occurrence of præcordial pulsation.

Dr. Shakespeare said that he had been struck with one point of great interest in connection with inflammation of the lining coats of the pulmonary artery, as evinced by the vegetations. These growths are very rarely found in the venous current. He had certainly never seen any other specimen, although he did not doubt that some had been seen or reported by other observers. Arterial blood seemed a requisite for the evolution of such diseased action. Evidently the site of the perforation being just below the aortic and pulmonary valves, brought about just this necessary pre-requisite, viz., abundance of arterial blood with the venous.

Dr. Wilson called attention to the evident relation between the incomplete ventricular septum and the condition of the pulmonary artery, which is greatly dilated and atheromatous, and presents the appearance often met with in the aorta, very rarely in this vessel. The wall of the right heart is relatively thickened. This fact, together with the position of the opening in the inter ventricular wall, which favors the flow of the blood from the left ventricle toward the pulmonary artery, renders it probably almost certain that the more forcible contraction of the left heart has constantly forced a portion of its arterial blood into the right heart, thus increasing the current entering the pulmonary artery and occasioning, 1st, hypertrophy of the right ventricle, and 2d, a sub-acute inflammatory process in the pulmonary artery itself, in consequence of the increased volume and force of the blood current. Dr. Shakspeare's observation that such growths as are here seen require for their existence arterial blood, is in accordance with this view.

Sarcoma of the Prostate Gland.

Presented by Dr. W. E. Hughes.

The specimen which I have the pleasure of presenting to you this evening was taken from a patient in the University Hospital, under the care of Dr. F. R. Wharton.

W. C., aged 35 years, admitted to the University Hospital suffering from retention of urine. Before his admission numerous unsuccessful attempts had been made to empty the bladder by means of a catheter. On admission the patient complained of much pain in the hypogastric region, which was the seat of a smooth, rounded swelling, reaching almost to the umbilicus. He stated that he had gonorrhœa some years previously, which had been followed by a troublesome stricture, which had been perfectly relieved by the passage of bougies. For more than a year previous to his admission he had suffered at irregular intervals, from difficulty in urination. The urine had never been bloody, but its passage had often been attended by great pain. It was found impossible, on account of numerous false passages, to introduce a catheter into the bladder. On introducing a finger into the rectum the prostate was felt smooth, rounded and immensely enlarged. The patient was put to bed, ordered suppositories of belladonna and opium, and to have a warm poultice applied to the abdomen. This treatment relieved him almost immediately, and urination became freer. For a few days he did well, but the difficulty in urination soon began to increase, and by the fifth day after his admission the symptoms had become so urgent that it was deemed advisable to repeat the attempt to pass the catheter. This attempt was as futile as the first. Then aspiration of the bladder through the abdominal walls was attempted, but only a small quantity of blood was obtained. In introducing the canula it gave the sensation of passing into a solid body, and careful palpation revealed the fact that there really was a solid body apparently occupying the whole bladder. It was now decided to open the urethra at the base of the bladder, through the perineum, and the operation, known as Cock's was selected. The operation was followed by the escape of a small amount of urine. After this the patient did well, with the exception of an attack of dysentery, until the ninth day after the operation, when peritonitis suddenly developed. He died on the following day.

Autopsy (two hours after death).—Upon opening the abdomen, a thick, yellowish-red, purulent liquid, having a urinous odor, was found, bathing the intestines, the walls of which were everywhere bound together by recent adhesions. The omentum was in places firmly adherent to the intestines, and

contained numerous, irregular, nodulated masses, varying in size from that of a pea to that of a hen's egg. These masses, on section, presented a whitish-yellow color. In the lower part of the abdominal cavity was a large, irregularly shaped tumor, firmly adherent to the small intestines, colon, omentum, and walls of the pelvis. On careful dissection the tumor was found to originate in the prostate gland. On section it presented, in parts, the characteristics of schirrus, in others, those of encephaloid. No trace of normal prostate gland, nor seminal vesicles could be discovered. The bladder, containing a few ounces of urine, was found in front of the upper portion of the growth, its upper boundary almost on a line with the umbilicus. Its anterior wall was apparently perfectly normal, its posterior wall, resting on the tumor, was thickened, raised, red and velvety. The ureters were normal, and opened in the usual position. The urethra, as far as could be seen, ran along the anterior surface of the tumor, and was not involved by it. The weight of the growth was five pounds, two ounces. The kidneys, stomach, lungs and intestines were normal. The peritoneum and capsules of the liver and spleen contained several secondary growths. The brain was not examined. Microscopic examination showed the growths to be a typical, small, round-celled sarcoma. The secondary deposits were similar in structure to the primary growth. The sub-mucous and muscular tissues of the bladder wall were somewhat infiltrated. The growths in the capsules of the liver and spleen had commenced to penetrate those organs.

Melanotic Sarcoma of Orbit, with Metastases to Liver, etc.

Presented by Dr. Shakespeare.

The patient was an elderly woman, who had been operated upon by Dr. Heyl, at the Episcopal Hospital, some six months before death, the whole contents of the orbit having been then thoroughly removed. Recurrence took place, the cavity being filled with a black, fungating mass; the left nostril gave vent to a blackish discharge, and the various internal organs became involved, notably the liver. Death took place from exhaustion. Most of the metastases are entirely melanotic, but some in the liver show, at their periphery a distinct, whitish zone. Dr. Shakespeare remarked upon the singular fact that orbital growths were usually melanotic, although they might not spring from the choroid coat of the eye, as in this case, where all pigmental structures had been removed many months ago.

Editorial Department.

Periscope.

Gastrostomy.

The Paris correspondent of the *Lancet* thus writes concerning this very interesting case:—

A cursory mention was made in the *Lancet* of Dr. Felizet's case of gastrostomy. The patient is now convalescent, and I will now complete the account of this case by a description of the operation and the subsequent treatment. Peter Genisca, for such is the name of this spoon-swallower, is a young Swiss of nineteen years of age. On the night of Sunday, Sept. 10th, he was amusing the customers of the *café*, where he was employed, by introducing a long spoon, such as is used for stirring coffee when served in glasses, into the œsophagus, pushing it as far down as he could and then withdrawing it. The performance was brought to an abrupt ending by the spoon slipping out of his fingers and disappearing down the alimentary canal. The following morning he was seen at the hospital by M. Felizet. Palpation revealed the existence of a foreign body, which projected in the left hypochondrium. Pressure upon this spot was painful, and caused a pricking sensation below the liver. The patient complained also of a feeling of constriction in the epigastrium, of difficulty of breathing, and of a painful sensation with each movement of the diaphragm. There was a constant flow of saliva and mucus from the mouth. Opium and ice were given to allay the pain, but in spite of this no sleep could be obtained, and bilious vomiting set in. This symptom, together with the patient's anxiety and suffering, decided M. Felizet to operate. In order to lessen the chance of the escape of any liquids from the stomach into the peritoneum, and to manipulate the abdominal organs as little as possible, the following plan was devised: A small india rubber tube was introduced through one nostril into the stomach. The outside extremity terminated in a **Y**-shaped branch, upon one division of which was a funnel, while the other was in communication by means of a tube with a recipient, containing ether. To begin with, the stomach was washed out by pouring a solution of bicarbonate of soda into the funnel, and then depressing the end of the tube below the level of that organ, so as to act as a syphon. The patient was then brought under chloroform, and the operation continued with antiseptic precautions. An incision was made, seven centimetres long, parallel to and one and a half centimetres below the edge of the false ribs, extending from the line of hepatic dullness, three centimetres below and external to the xiphoid appendix, to a point on the left side, on a level with the junction of the ninth and tenth costal cartilages. The sheath of the rectus and some of its fibres were divided, and the peritoneum exposed. Hemorrhage having been entirely arrested by torsion and ligature, the recipient containing ether was plunged into a vessel of water at 60° Centigrade, and the stomach at once became distended by the vapor, and the peritoneum, being divided upon a director, protruded through the wound. Ten sutures in all were then made to fix the stomach to the abdominal wall, the ether being allowed to escape, in order to ascertain whether the juxtaposition of the surface was

complete. One spot appearing defective the stomach was distended again, and another suture inserted. An incision, six centimetres in length, was then made in the axis of the wound. After the vapor had escaped, the stomach was found to be perfectly clean and empty. The spoon was felt, lying transversely across the stomach, with one end in the pylorus and the other in the greater curvature; it was then extracted without difficulty. After the operation the patient was kept under the influence of morphia by small hypodermic injections. Tea and rum were given as a drink, with small pieces of ice. Antiseptic dressings were applied. The after effects of the operation were not serious. There was no fever or tenderness of the abdomen. The most distressing symptom was great thirst, but this was relieved most satisfactorily by enemata of cold water. Notwithstanding the dressings, the liquids swallowed passed through the wound. On the fourteenth day a little milk was given, but this oozed through the dressings, and was not renewed. On the fifteenth some meat was tried, but caused uneasiness. On the first of October a considerable portion of the wound had healed, and all that remains is a fistulous opening, closed by a pad. The patient eats meat, vegetables and pastry.

Foreign Bodies Swallowed.

At a recent meeting of the Boston Society for Medical Observation (Boston *Med. and Surg. Jour.*) Dr. Reynolds introduced the subject of swallowing foreign bodies, and said: The profession possesses in its classical treatises accounts of an endless variety of foreign bodies that have passed in safety through the alimentary canal. When, however, unusually large or very ill-shaped bodies are to encounter the delicate structures of the intestine in very young subjects, the attendant often finds it hard to put once more unlimited confidence in the natural powers. It is, therefore, perhaps, not unwise to place on record any such instances.

A girl of eight years, holding between her lips a smooth, oblong stone, as large as the last phalanx of an adult thumb, suddenly threw herself back on the floor, and in so doing swallowed the stone. The enemy was voided at stool between forty and fifty hours later. The child ate heartily after the accident, took no medicine, and suffered neither pain nor disturbance of health. Unfortunately the stone cannot be exhibited, as the nurse, thoughtlessly, threw it away. It was, however, well known, and was easily recognized.

Dr. H. I. Bowditch related a case in which a little girl, three years old, swallowed a leaden button. The parents, being much alarmed, gave her, with the consent of a physician, a dose of castor oil. Afterward nothing special was done, and at the end of a week the button was passed from the anus without suffering. Dr. Bowditch said that in his opinion the oil was unnecessary. Certainly repeated dosing, from the liability to produce ill health, should be avoided. A plenty of substantial, rather loosening food, so as to keep the bowels easily and normally opened, was better. Bullets often lie in various parts of the body, and are harmless. Why, then, be alarmed in such a case as the above?

Dr. Brown said it was bad practice to give cathartics or watery substances in such cases. The aim should be to solidify the fæces so as to envelop the object, and milk would be a good diet for this purpose.

Dr. Ingalls reported a case in which a man had swallowed a peach stone. It had come as far as the rectum, but could not be passed further. As it was too high to be reached with the finger, the patient was etherized, and the stone was extracted by the aid of forceps.

Dr. Bush said that it was the custom with persons who attempted to pass spurious coin to swallow them, often, to avoid detection. In such cases their diet was composed of hard-boiled eggs, they having found by experience that this diet rendered the foreign body harmless, by enveloping it in a coat, and in about three days the coin would be found in the fæces.

Dr. Fitz said that if the junction of the pharynx with the œsophagus was the narrowest part of the alimentary canal, anything which will pass this point will pass through the other parts without trouble. Hence if a body of good shape has been actually swallowed, no alarm need be felt.

Lesions of the Teeth in Locomotor Ataxy.

The *Medical Times and Gazette* says: At the meeting of the French Association for the Advancement of Science, on August 30th, a communication was made by M. Th. David, upon lesions of the teeth in locomotor ataxy. The paper was based upon the observation of a single case, and the following are the most important of the conclusions arrived at from an attentive study of it: The alteration consisted of a rapid decay of the anterior part of the crown of almost all the teeth. The altered substance assumed the consistence of touchwood and a reddish color. The enamel still retained its polish, but not its hardness. Beneath those parts the pulp had produced a new layer of secondary dentine, and in most of the front teeth the pulp cavity was filled up. These alterations had nothing in common with caries, and must be referred to nutritive disturbance resulting from the lesion of the central nervous system. The changes are analogous to those which have already been observed to take place in the nails in the course of locomotor ataxy; they would thus establish a pathological relationship between organs already connected by a common epithelial origin. Locally, these alterations recognize for their immediate cause a functional disturbance or a lesion of the dental pulp. The atrophy which has been shown to exist would be quite comparable to that which is observed in the eye under similar circumstances. Whence the final conclusion that we must attribute to the dental pulp the physiological significance of a sensory organ.

—Dr. Sharp, of Salem, has in his possession a deed signed by William Penn, in February, 1672. It is in a good state of preservation.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D.,
JOSEPH F. EDWARDS, M.D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

After Jan. 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, will be commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, $2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for strictly in advance and directly to this office.

THE SURGEON GENERAL'S REPORT.

The Annual Report of the Surgeon General U. S. A., places the average mean strength of our army at 20,778 white, 2265 colored, and 245 Indian troops. The total number of cases on the sick list was, among the whites 1679 per thousand, among the colored 1810 per thousand.

Of the whites the average number constantly on sick report during the year was 45 per thousand of mean strength, whereas among the colored troops it was 44 per thousand—the difference being unappreciable.

The deaths among the white troops were at the annual rate of 10 per thousand, of whom 7 per thousand died of disease, and 3 per thousand of wounds, accidents or injuries. The colored soldiers died at the annual rate of 11 per thousand, of which number 7 died of disease and four of wounds.

Of Bureau work it is stated that during the past fiscal year 2693 Monthly Reports of Sick and Wounded have been received from the medical officers in charge of the various posts and stations. These have been examined, consolidated on statistical sheets for use, and the deaths and discharges entered in the appropriate alphabetical registers. 955 Reports of the Medical Examination of Recruits were received and filed, and 823 Monthly Meteorological Reports were received from medical officers and transmitted to the Chief Signal Officer of the Army, for his use.

The work in the Record and Pension Division continues something enormous. Not less than 61,630 official demands for information as to the cause of death in the case of deceased soldiers and the hospital record of invalids was made upon this department! This was nearly 7000 in excess of the previous year. There are now pending in the office over 83,000 of such inquiries, waiting to be disposed of! In connection with this subject the Surgeon General makes a significant observation, in these words:—

"I would also refer in this connection to a progressive increase in the difficulty of search for record of the hospital treatment of soldiers who served in the late war. As time elapses

claimants appear to be more than ever unable to furnish definite information concerning the date and place of their treatment. There is much evidence at hand to establish the fact that this difficulty does not arise from defective memory alone. It is to be regretted that there is too often a manifest failure on the part of those preparing declarations for pensions in pressing inquiries upon these important points, as it is the cause of much of the delay hitherto charged to this office."

In speaking of the library, the Report very justly urges that no advantage would accrue from merging this library with any other; its size and importance, and the demands made upon it being such as to require the services of a specially skilled medical officer to make it as useful as it should be, and to preserve for it the interest of the medical profession of the country, to which much of its completeness is due.

The third surgical volume of the History of the War is ready in manuscript, and will be laid before Congress promptly. The Museum, during the year, was visited by 13,250 persons, giving strong testimony to the value in which it is held. A strong appeal is made that its unequaled collections shall have erected for their conservation a fire-proof building. It is justly urged that this collection has attained a world-wide celebrity; is second to none in the number and value of specimens illustrating military surgery and the diseases of armies, while its sphere of practical usefulness to the medical profession of the country is unlimited. It is therefore hoped that Congress may be induced to appreciate its great value and importance, and provide for the fire-proof building required to place the collections beyond the chance of loss or injury.

Notices of the deaths of medical officers and their army records are added.

The Report is a satisfactory one in every respect, and is convincing testimony of the efficiency and scientific training of the medical staff of our army. Its recommendations should receive the early and favorable attention of the Congressional committees. So little intelligent interest, however, has been manifested by the present Congress in medical and sanitary matters that we are not sanguine as to its action.

THE MANUFACTURE OF DYNAMITE.

On the coast of Ayrshire, a few miles south of Ardrossan, are located the works of the British Dynamite Company. Though not in any way offensive, as regards bad odors, nor inimical to health, nor injurious to either animal or vegetable life, yet they are located one mile from the nearest village, no doubt with a view of reducing the loss of life in the event of an explosion, though so perfect are the police regulations of the place itself, that the danger is almost nil.

Some two hundred and fifty men and women are employed in the works, and when they enter the gates in the morning, they become virtually prisoners for the day; but their healthy, contented faces and cheery voices give ample evidence that they like the work and do not fret at their volutary confinement.

The day's work is commenced by all hands changing their ordinary clothing, for a uniform, differing for each gang, and each distinctive of the special work to be performed by this particular gang.

This uniform plays an important part in the safety precautions of the establishment.

Realizing that accidents usually occur in dangerous occupations, on account of some one undertaking to do something with which he is not thoroughly familiar, the management have adopted these distinctive uniforms (in one instance bright red), so that the police can tell at a glance whether any one is out of his or her province.

Four men from the county police force, paid by the company, are constantly patrolling the premises (which cover an area of a square mile), and they can neither speak nor be spoken to.

The superintendent is a man intimately acquainted with all the theoretical and practical aspects of the question of manufacture, besides which, at irregular and uncertain intervals a government official visits the place to see that the Acts of Parliament relative to the manufacture of dynamite are faithfully carried out.

The process followed in the manufacture is based on the discovery of Mr. Noble, that by the use of an inert substance the power of the

explosive is not lessened, while the risk attending its application is reduced.

The substance used is a porous, silicious earth, resembling flour, into which nitro-glycerine is poured and by it absorbed, when the compound is passed through various processes, each with a view of lessening the danger of handling. It is then made up into cartridges of various lengths and power. The cartridge material divested of the agency of a detonator may be handled and subjected to percussion without explosion.

There are limits as to the quantity which may be sent out at any one time, and there are rules laid down for the arrangement no less than for the size of the cases holding the material. That it is a profitable undertaking in which the company are engaged is apparent from the high premium on the original shares; and that their product has become a "resource of civilization" is shown by the demand for it from every part of the globe where man, warring with nature, is uprooting the stumps of trees that hinder the progress of his plow, leveling the rock that comes between him and a straight path, unloosening from its firm foundation the stone that is to build his house, breaking into the seam of the coal that is to cook his dinner, or making deep and navigable the stream that gives him communication with his neighbor.

THE AMERICAN vs. THE EUROPEAN PROFESSION.

In reading the foreign journals one cannot but be struck by the frequency with which he encounters reports of remarkable operations and clinical histories of peculiar phases of disease, as compared with similar reports in our own medical periodicals.

We have often reflected on this, and wondered at the cause.

The body of an American is formed on the same principles, and subject to the same pathological and physiological laws as that of the European; it is but reasonable, then, to suppose that it would be affected by the same injurious agencies in the same morbid manner.

We have in this country a large number of persons, and a great army of physicians; the same diseased conditions must obtain, and the necessity for similar surgical procedures must exist.

Why then is it that in English journals we read of nephrotomy and nephrectomy, of gastrotomy and œsophagotomy, of removal of the larynx and the like.

Why do we find reported cases of "acute traumatic malignancy;" why do we read lectures on "the pre-cancerous stage of cancer," and innumerable other odd and singular phases of diseased condition, evidencing, as they do, acute observation of facts and accurate generalization from them.

Our profession, as a body, will compare favorably with that of any nation in the world. We have original thinkers, accurate observers, and broad generalizers. We are not any more conservative than our brethren of other countries.

Why, then, is it that we do not read in our journals similar cases to those reported in the medical press of England, for instance?

We imagine that the explanation is to be found in the fact that the physicians of this country do not thoroughly realize the importance of the medical press, and, therefore, do not cultivate it as they should.

This is one reason; this is why we do not read more practical clinical reports of unusual cases; and the unfortunate habit of looking to older countries for innovations in practice makes us hesitate to try new operations until their utility has been demonstrated for us.

There are some American physicians who write too much, but the great majority do not write enough.

Medical journals are the vehicles of interchange of thought and experience between the members of the profession, and a physician should make it a rule always to report every case that may occur in his practice in which any phenomena may present themselves that he does not find recorded in his text-books.

But he should be short and explicit. Many an otherwise good communication has been rendered worthless by being too *long-winded*; the

valuable points have been smothered in a lot of trash.

When a man feels sure that he has something *new* to report, he should reflect how he can say what he has to say in as few words as possible. He will thus prepare an article that will be readable as well as valuable, and will not encroach unnecessarily on the too limited space of a good journal.

Physicians should likewise cultivate the habit of independent thought and reasoning in their practice, and should not, as so many do, practice strictly according to the rules laid down in books.

Short, practical communications are always of value, and the profession of our country should make it a rule to prepare them frequently.

Notes and Comments.

Etiology of Hemorrhagic Smallpox.

At the recent scientific Congrès at Rochelle, M. L. H. Petit made a very important communication on the etiology of hemorrhagic variola. He considers that the visceral lesions found in this form of variola are rather the causes than the effects of the hemorrhagic variety of the disease. The same might also be said for other malign forms of this and other diseases.

But distinction must be made between old lesions (diverse forms of degeneration, steatosis, sclerosis, etc.) and those of more recent origin (interstitial hemorrhage). The general lesions, whether causing or themselves caused by the general morbid condition of the system, act on smallpox just as they do in traumatic lesions, that is, through the modifications induced in the blood and tissues, particularly in the capillaries. Among the subjects predisposed to the hemorrhagic variety of smallpox might be ranged those who have before suffered from affections of the spleen, heart, kidneys, etc., or from diseases capable of inducing alterations in these viscera, such as rheumatism, scarlatina, malarial affections, alcoholism, etc. It is for this reason that the prognosis is much less favorable in patients presenting these morbid conditions. In the discussion which followed, M. Verneuil remarked that regarding the malignity of maladies two elements should always be considered: 1st, the intensity of the poison, and 2d, the vital resistance of the subject attacked. It has been remarked by M. Leudet, that the frequency of the hemorrhagic variety is not more marked during an epidemic than at other times, and he thence concluded that in the development of this form of variola the condition of the subject plays a more important part than the intensity of the poison.

Ovariotomy in Italy.

In the *Raccoglitore Medico*, of the 20th of July, Dr. Peruzzi publishes a note on the third hundred cases of ovariotomy in Italy. He shows that while nineteen years were taken up to complete the first series of one hundred cases, the second only took two years and a half, and the third twenty-three months. The third series was performed by forty-six operators, of whom twenty-eight only had one case each; seven had only two each; and Dr. Margary, of Turin, who had the largest number of cases, only eight. The result was seventy-three recoveries and twenty-six deaths. In the second hundred, there were thirty-six deaths, and in the first sixty-one; a very satisfactory proof that as experience has increased mortality has diminished. Of incomplete or partial operations, during the progress of the last hundred completed operations, there were nine, with five recoveries and four deaths. Of removal of uterine tumor, classed together as supra-vaginal laparo-hysterotomy, there were twenty-seven cases, with only seven recoveries to twenty deaths.

Cardiac Form of Typhoid Fever.

At the Congrès at Rochelle, M. Bernheim, of Nancy, read an interesting memoir on this subject. Under the above designation he places those cases in which, without notable organic alteration of the heart itself or any pulmonary complication of sufficient gravity to explain the fact, the pulse becomes small, very frequent and depressible, and the patient succumbs under this paralytic acceleration of the action of the heart, which may occur at the debut of the malady, either with or without concomitant nervous adynamia, or at a more or less advanced period of its evolution.

In such cases the temperature is not very high; it may be normal or even hypo-normal. M. Bernheim is of opinion that this state of asystole of nervous origin is due to the direct action of the poison or typic microbe, on the centre of cardiac innervation.

Generally in typhoid fever the pulse is less frequent than in other febrile conditions, as if the typic poison, like digitalis, had a slowing-up action on the heart; it may then be possible

that the poison, when too concentrated, should have the same action on the heart as a toxic dose of digitalis producing a paralytic acceleration of its action.

This theory would explain the fact, noted by M. Bernheim, that digitalis in such cases is not only inefficacious but dangerous, and that given even in preventive doses it does not prevent the manifestation of the cardiac form of the disease.

Finally, sudden death in certain cases of typhoid fever, where no appreciable alteration of the heart can be found at the autopsy, may be due to the sudden concentration of the poison on the cardiac centre.

Caution About a Popular Toothache Remedy.

A formula frequently used to relieve toothache, is the following:—

℞. Spts. chloroformi,
" Æth. sulph.,
" Camph.,
Tr. opii,
" iodinii, āā fʒj.

A pledget of cotton saturated with this mixture is placed in the hollow of the aching tooth. It was tried once by Dr. Charles H. Miller, of Peabody, Kansas, who reports the case in the *Southern Clinic*, in a stout young girl of 18, who used the remedy several times, and finally went into a stupor, from which it took many hours of hard work to arouse her. He, therefore, cautions against prescribing it too liberally or too carelessly, especially where the patient will be left in entire and undisputed possession.

Quinoline (Quinoléine).

The principal physiological effects of this newly discovered medicament are: 1st. Notable fall of temperature (Donath, von Jaksch, Black and Loiman). 2d. Gastric derangement (nausea and vomiting), ringing in the ears, etc. In a toxic dose there is frequency of respiration, diminution, and finally abolition of reflex excitability, followed by complete paralysis and death (often with œdema and hyperæmia of the lungs). Quinoline and its salts have antiseptic properties. It would seem to serve in certain cases as a substitute for quinine, and is much less costly.

The tartrate and the chlorhydrate of quinoléine have been used hypodermically. The chlorhydrate in hypodermic injection is apt to induce local irritation, according to von Jaksch, who introduced four grains at a dose. The tartrate is preferable for hypodermic use; it is soluble in water and alcohol, and does not often produce local accidents.

The hypodermic dose for the adult is from five to fifteen grains.

The salts of quinoléine have been employed with variable results in intermittent fever, neuralgia, typhoid fever, whooping cough, pneumonia, erysipelas, septicæmia, etc. Further researches and clinical experimentation will be required before the therapeutic value of the drug can be accurately determined.

Tincture of Iron and Chlorate of Potash in Scarlet Fever.

In the Glasgow *Medical Journal*, Dr. John S. Main furnishes additional evidence of the good effects of the tincture of the perchloride of iron and chlorate of potash, which he generally combined with glycerine. The chlorate of potash should be dissolved in hot water, as it is very insoluble in cold.

The theory of this medicine in scarlet fever has been very well described in an article in the *Lancet*, of 20th of August, 1878, by Dr. Renfrew. He describes it thus: "This mixture contains chlorine, hydrochloric acid, iron and chlorate of potash. The acid supplies acid to the blood, which is in a sub-acid condition; the iron improves the red discs, which are in a black and melanosed state; the chlorate of potash supplies oxygen to assist in oxydizing the disintegrated material in the blood, where it floats freely."

Eyelashes in Anterior Chamber of Eye.

In the *Lancet*, Mr. Williamson tells of a boy, aged 8, who was stabbed in the eye with a pocket knife; when seen, two weeks afterward, there was but slight inflammation and very little increase of vascularity in the ciliary region. On the front of the cornea, in the area of the pupil, there was a cicatrix, and inside the anterior chamber were what appeared to be six or seven hairs, lying vertically. Mr. Williamson made an incision at the upper part of the cornea, and excised a piece of the iris. The hairs were then drawn out with a pair of fine forceps; one hair that escaped the forceps was caught by a Tyrrell's hook. All went on well after the operation, and the lad has now good sight with the injured eye.

Under the microscope the hairs were found to taper to a point at one end, and to have a root at the other. They were about the length of the eyelashes. The lid was carefully examined for a gap in the line of lashes, but none was found. Probably the knife was a blunt one, and caught the lashes about the middle, doubling them up and drawing them out by the roots. They would

then be carried on the end of the blade into the anterior chamber, remaining there when the knife was withdrawn.

It is remarkable that the hairs caused so little irritation, although some of them actually pierced the iris.

Traumatic Stenosis of Trachea.

At a recent meeting of the Medical Society of the County of Albany, Dr. N. L. Snow (*Annals*) reported the case of a stout, hearty man, who was caught between two cars. The point injured was the upper part of the chest, which was excoriated, and there was flattening on the right side, with undue prominence on the left. Anodynes afforded relief. He was chiefly troubled with dyspnœa. This would trouble him in paroxysms, but always yielded to anodynes and hot fomentation. On the twenty-ninth day great dyspnœa supervened, from which he died the next morning. At the autopsy, a stricture of the trachea was found, situated about one and a half inches above the bifurcation.

Tympanites in cases of Fibroid Tumors of the Uterus.

Distressing tympanites, remarks M. Chéron, in the *Jour. de Med. de Paris*, is frequently observed in cases where rather large uterine fibroids exercise more or less pressure on the rectum.

In such cases, very frequently, the usual remedial agents are of no benefit, and prepared charcoal and chalk, magnesia and carminatives do not relieve the symptoms. When such is the case, M. Chéron pursues the following course of treatment: 1st. Complete suppression of wine and every form of alcohol. Water or some of the mineral waters at meals. 2d. To take four times daily a tablespoonful of the following lotion:—

℞.	Tr. valerian,	℥ ss	
	Syr. ætheris (Fr Cod.)	℥ iss	
	Aq. menth. piperit,	℥ j	
	Aq. destill.	℥ iv.	M.

3d. Rub in, night and morning, over the abdominal region a part about as large as a nut of the following ointment:—

℞.	Ext. bryon,	℥ j	
	Ung. simpl.	℥ j.	M.

Under the influence of this treatment, after a few days there is a notable diminution in the distressing symptoms.

The amelioration will be rarely durable, as the cause always exists, but by careful attention to diet, the use of mineral waters, etc., considerable relief may almost always be obtained.

Ulcerations of the Pharynx in Phthisis.

We read in the Paris *Médical*, that M. Schiffern relates a case where cure of a tuberculous ulceration at the arytenoid region was obtained by the insufflation of finely pulverized iodoform.

This was done by means of a rubber ball, similar to those on ordinary syringes, attached to a tube of caoutchouc. The author made two or three insufflations daily, each time of 30 centigrams (gr. v) of iodoform.

The medicament seems to form a thick covering over the ulcer and is not dislodged by coughing.

When the ulcerations are situated on the epiglottis he applies the following, with a camel's-hair pencil:—

℞.	Iodoform,	℥ ss–℥ iss	
	Collodion,	℥ ss.	M.

He avoids the peculiar odor of iodoform by placing fragments of tonka bean in the bottle which contains it.

Absorption by the Skin.

At a recent meeting of the Académie, M. Aubert read an important memoir on this subject, arriving at the following conclusions:—

1st. Substances dissolved in water may penetrate the epidermis without apparent external erosion. 2d. Nevertheless, the one condition essential to the accomplishment of this penetration appears to be an epidermic effraction about the hair follicles. 3d. In his experiments he has found that the penetration of dissolved substances takes place only over the regions covered with hair. 4th. All conditions which induce traction on the hairs, such as friction, etc., favor absorption. 5th. Fine skin and a thin epidermis are rather unfavorable conditions, on account of the feeble hair development in these regions; the total absence of hair is also a very unfavorable condition as regards absorption. 6th. It is possible that a small proportion of any soluble substance may penetrate the epidermis, and this means of absorption may be utilized by baths or without. To bring about absorption it will be necessary, both before and during the time the substance is in contact with the skin, to make prolonged frictions with the palm of the hand over the cutaneous surface, especially over regions covered with hair. The only inconvenience attending such practice is very moderate inflammation and a slight degree of redness, generally localized at the points where the hairs emerge. 7th. The simple bath, without friction, even prolonged (for two hours in several cases), cannot be depended on to induce the absorption of the smallest particle of the substance in solution.

Diagnostic Importance of Rectal Examination in Stone of the Bladder.

R. Volkmann, who made the above subject a special study, advises, that with relaxed abdominal walls, under deep narcosis, especially in slim individuals of youthful age, while introducing one finger into the rectum and applying the palmar surface of the right hand to the abdomen, the stone should be pushed up to the pubic bone and held here with the latter hand. He says it were then easily possible to grasp it perfectly, and he actually demonstrated the fact to his students, a number of whom he permitted to get hold of the stone. (*Arch. f. Chirurg.*, 1882, No. 11.) If the stone is not too large, it can be lifted up with the soft parts, and so high that it could be tied with a ligature, a fact which V. mentions, not to recommend it as an operation for stone, but to be made use of in movable cystic tumors, as in cases of papillomata with long pedicle, or in cases of myoma, which could well be extirpated in such a manner.

Miners' Nystagmus.

The *Med. Times and Gaz.* says that M. Dransart has lately read a paper on this subject. His conclusions are that the disease is due to a paresis of the organs concerned in the elevation of the eyes (both muscles and nerves), resulting from fatigue of the elevators, caused by the nature of the work (in low galleries, etc.); that it is independent of any central nervous lesion, and that it is curable.

A Case of Septicæmia.

Dr. G. Stanley Murray reports, in the *Lancet*, the case of a young man, aged 27, who died with all the symptoms of septicæmia, after having had twenty-two decayed teeth removed within three days. He had a tendency to phthisis, and was much enfeebled before the teeth were removed.

Correspondence.

Sixteen Grains of Sulphate of Morphia Taken at One Time—Recovery.

Ed. Med. and Surg. Reporter:—

On November 9th, 1882, at 10 A. M., I was called in consultation with Dr. Yingling, of Huntington, Ind., to see Miss Eva S., aged 28, domestic, who had been found lying on the ground in the rear of the house, in an unconscious condition.

As she was evidently profoundly narcotized, and had frequently threatened to "put herself out of the way," we concluded we had no child's play in the case, if we would thwart her intent. Concluding she had taken the "morphine route," and as she could not swallow, and as we had no time to lose, we gave her hypodermically fld. ext. belladonna, gtt. v, and carb. ammonia, gr. iij (sulph. atropia was not at hand). The pupils dilated slightly and respiration and circulation were somewhat improved, and at the expiration of two hours we repeated the injection. This caused a very marked improvement of all the symptoms, and our patient was so far recovered as to be able to take her treatment per orem. This consisted of the belladonna and ammonia, to which was added a very strong infusion of coffee. These remedies were used for forty-eight hours, when she was convalescent and further attendance discontinued. I should have stated that a saline cathartic was given as soon as it could be swallowed, and acted promptly. On Nov. 20th she called at my office, and from her I learned the following:—

1st. She had never taken opium or any of its preparations before the date above named.

2d. The quantity taken was sixteen grains of morphia sulph., at a single dose.

3d. Time of taking dose, 9 P. M., Nov. 8.

4th. She had eaten a very light supper four hours before.

5th. She did not vomit after taking the drug, nor take anything to counteract its effects.

6th. She did not become fully conscious until ten days after.

That she should have recovered, under all the circumstances, appears to me quite remarkable.

Wm. C. Chafee, M.D.

Huntington, Ind., Nov. 21st, 1882.

Death During Parturition.

Ed. Med. and Surg. Reporter:—

A singular, sudden and sad death occurred in our village on Sept. 27th, 1882, which I ask you to please publish in your "Correspondence Column." Late in the evening of Sept. 26th, Mrs. G., of this place, a small, weakly woman, aged 28, was taken in her sixth confinement. All her previous labors were of a tedious nature, especially the fifth, which she got through with the greatest difficulty, and since which time had had several attacks of hemorrhage of the lungs. Saw patient about 7 A.M. of 26th; found the os uteri but slightly dilated, though indications bid fair for a safe delivery; in a few hours the waters were prematurely discharged, *i. e.*, without dilatation. And here came the "tug of war." Found the left hand by side of vertex, engaging the small unyielding os; delivery by version, the usual way, was now the alternative; succeeded in introducing index finger; feet could be touched, but, failing to introduce the hand into the internal cavity, on account of the contracted condition, they could not be grasped until several hours of valuable time had elapsed. But even then, by every manipulation, the feet (or foot) could not be brought down; the fundus uteri remaining high in the epigastrium, and so firm the resistance, that I had some thoughts of a plural birth. With every effort toward version there was considerable hemorrhage, and on account of faintness and cold extremities, I was forced to desist from further manipulation; ergot was freely administered, and all means of artificial heat applied; hemorrhage was promptly

arrested, but pulse small and rapid, and whole surface bathed in a cold perspiration ; gave frequent doses of quinine and brandy with the ergot, kept back the protruding member, and let the head engage the superior strait, hoping to sustain the powers of life, and anxiously looking for reaction ; child not perceptibly viable at any time ; pains had almost entirely ceased since first hemorrhage was noticed. After utilizing almost every instrument in my possession, as a dilator to the unyielding os, preparatory to using forceps, I decided to give the patient an hour's rest, hoping thereby to be rewarded by more strength and better pains. She, however, rallied but little. At about 7 P.M. I applied forceps, although the os uteri was but little dilated ; fœtus seemed immovable, and patient was passing from one fainting spell into another, until I withheld further effort, but continued the ergot, quinine, artificial heat, etc. ; chloroform had been given before forceps were applied. Dr. Bridwell being called in consultation, used skillful manipulation, applied forceps, etc., but patient again sank, followed by syncope, collapse, and died at 11.20 P.M., of 27th.

Post-mortem.—A very large child, extracted by Cæsarean operation ; hemorrhage had filled and greatly distended uterine cavity; fundus reaching the diaphragm. The death in such cases cannot be attributable to the length of time, nor to the severity of the labor, as we, not unfrequently, have had labor lasting forty-eight hours, without serious results. Primarily, the cause may be due to general debility, while the immediate cause of death must have been uterine hemorrhage.

Fortunately such cases are of very rare occurrence.

W. H. Dowden, M.D.

Owensburgh, Ind.

The Action of Iodide of Potassium.

Ed. Med. and Surg. Reporter :—

In The Reporter for Nov. 11th, Dr. F. Shimonek, of Beaver Dam, Wis., relates a peculiar and unexpected result following the administration of 6 gr. of potassium iodide to a lady patient. To my mind, the reliability of the preparations manufactured by such chemists as Powers & Weightman preclude the probability of the results being due to any impurity in the preparation employed. Eliminating this question, *what was the cause of death* in this instance?

My explanation is not original, but based on the researches of Buchheim, and recorded by Bartholow, in the 2d edition of his "Materia Medica and Therapeutics" (p. 178). It is to the effect that at the points of elimination from the free mucous surfaces, chemical changes occur, resulting first in *ozone* being set free. The ozone now attacks the salt, decomposing it and freeing its *iodine*.

According to this explanation, inflammation of the mucous surfaces was produced, which in turn produced such an effect upon the nervous system as to bring about spasm of the glottis, which, in conjunction with an inflammatory condition of the broncho-pulmonary mucous membrane, accounted for the dyspnœa. As the drug is eliminated very rapidly (being detected in the saliva and in the urine in 15 minutes), I think the suddenness of the symptoms are thereby explained. The fact that former administrations produced somewhat similar symptoms would seem to indicate that at the time of the administration of the last dose the nervous system was in condition to readily respond to the action of the remedy ; in other words, that the final action may have presented itself in less time than would be necessary for the elimination of the iodide. I should be pleased to hear from others on this subject, especially as to the influence of the peculiar nervous system in such instances.

Poughkeepsie, N. Y. H. R. Powell, M.D.

Some Interesting and Unpleasant Cases in Practice.

ASPIRATION OF BLADDER—ENLARGED PROSTATE—DEATH.

Ed. Med. and Surg. Reporter :—

A man over 50 years of age, suffering from retention of urine from enlarged prostate, came under observation. Different forms of prostatic catheters, including the soft rubber, were used, but without effect. When the catheter was introduced it was firmly grasped by the prostatic urethra, and on withdrawal the eyes of the instrument were found filled with blood. These two facts, viz., immobility of the catheter when introduced deeply, together with bleeding on withdrawal gave rise to strong presumption of a false passage. It was then decided to aspirate in order to relieve the patient of his most urgent symptom.

Potain's instrument was employed, and on withdrawal suction was kept up to prevent any urine escaping from the needle into the cellular tissue. On the following day the catheter was again employed, but without success, and aspiration was again performed. Symptoms of peritonitis set in shortly afterwards, and on the following day the patient died. The autopsy showed a very much enlarged prostate, but no evidences of a false passage were noticed. There was no sign of peritonitis around the needle punctures, and very slight evidences of inflammation in any part of the peritoneal cavity. The bladder contained only a few ounces. There was no extravasation of urine. The case was interesting and painfully unpleasant and unsatisfactory in its termination. The autopsy unfortunately did not throw much light on it.

Shortly after this case was seen, another one, of enlarged prostate, with retention, came under observation. Several attempts were made to pass the catheter, but, as in the case recorded, the instrument was firmly held by the prostate, and on withdrawal the eyes were filled with blood. A final attempt was made and considerable force used, when the catheter passed the obstruction, and the anxious patient was gratified by a copious flow of urine.

These two cases are of more than common interest in regard to the treatment of retention of urine in cases of enlarged prostate, and the inference is that it is better to use a certain amount of force, at the risk of making a false passage, than to expose the patient to the dangers coincident to a distended bladder.

PUZZLING CASE OF INCARCERATED HERNIA—OPERATION—DEATH.

A man, 35 years of age, was seen after he had been suffering for a few days from what was supposed to be strangulated hernia. The patient gave the usual history of constipation and abdominal pain. An examination showed a peculiar swelling in the inguinal canal, not unlike what might be expected from hydrocele of the spermatic cord. It was not hard, and the finger could pass up the inguinal canal. It was considered best, on account of the urgency of the patient's condition, to operate and explore the canal. In doing so there was found to be a partially strangulated or incarcerated hernia at the left internal abdominal ring. The puzzling condition of the canal was due to fluid, the result of the hernia. The patient died shortly after the operation.

SOME OF THE DIFFICULTIES IN ASPIRATION OF THE CHEST.

A man, aged 70, suffered from chronic bronchitis and subsequently from pleurisy and empyema on the right side. Surgical interference was not attempted till the dyspnœa became oppressive. He was then aspirated, and about two quarts of foul smelling pus removed. Great relief followed the operation, and the patient was allowed to rest for a few days, when he was again aspirated to relieve the distress of breathing. On the afternoon of the same day it was decided to make a permanent opening and wash out the pleura. The usual incision was made at the point of aspiration, but no pus obtained. Another incision was made lower down and the precaution made to carry it pretty far into the chest, but still not a drop of pus was found. On the following day a swelling appeared below the chest wall, on the same side, but as the patient was moribund, no exploration was attempted. Unfortunately, no autopsy was held.

There are some pertinent questions which readily suggest themselves, such as the whereabouts of the fluid, inasmuch as only a limited amount was removed on the morning of the operation. The facts, unsatisfactory though they be, are respectfully submitted to the readers of the REPORTER, with the hope of bringing forward some suggestion.

One thing that painfully impressed itself on my mind was, do not aspirate shortly before making a permanent opening in the chest wall.

J. S. B.

NEWS AND MISCELLANY.

Artificial Food for Infants.

Infants ought properly to be raised on mother's milk, and nothing else, for the first year of their life. All mothers, however, do not survive childbirth; others have no milk; others have diseased breasts; and there are other good excuses, as well as a lot of poor ones, why mothers don't and can't nurse their infants. Some artificial food is therefore necessary. One to which our attention has been especially called is the Anglo Swiss Milk Food. It is prepared at Cham, Switzerland, by the Anglo Swiss Condensed Milk Company, and has the endorsement of a large number of practitioners who have tried it. Any of our readers who give it a fair trial will gladly be heard from through our columns, as our object is to give every such preparation its full and just praise, and no more.

Resurrectionists.

We have been lately regaled with a great sensation about the stealing of bodies from cemeteries for the purposes of dissection in medical colleges.

We have purposely refrained from making any allusion to the same at an earlier date, in order that we might speak calmly and unexcitedly of the affair. The course of events seems to indicate, as we had supposed at the first, that there are wheels within wheels, in this, as in most other sensations, and while we join with every right-minded man in denouncing the spoliation of graves, we reserve a final opinion on this *old and often used* sensation until we can tell all about it.

New Century Lectures.

Under the auspices of the Franklin Institute, a course of lectures with the above title is now being delivered. The first, by Miss Mary Hobart, of Boston, had for its subject, "How to Wash and Dress a Baby." The second was on "Cooking for the Sick." We most heartily commend these lectures. They are still further evidence of the interest that is gradually developing in this country in all that pertains directly or indirectly towards preventive medicine or hygiene.

It is well that the public should be taught how great is the power of proper washing, dressing and cooking in the maintenance of health.

Diphtheria in Schools.

A very severe epidemic of diphtheria has broken out in the town of Hamilton, N. Y. Two institutions of education are located there, and in one of them several deaths have occurred. The Faculty are debating the question of closing the institution. Their duty is plain. They should at once close the school and send away all scholars not sick. When the last case has died or recovered, the institution should receive a thorough disinfection, first chemically, and subsequently by means of an abundance of soap and water and pure air, when the exercises can be safely resumed.

A Conscienceless Physician.

A prominent physician of Aiken county, S. C., was arrested on the 5th inst. on the charge of having committed a diabolical crime against his own wife. The infuriated populace proceeded to the jail and threatened lynch law, but were dissuaded from their purpose. We trust this wretch will receive the full punishment prescribed by law, if, indeed, he be guilty of the alleged act.

The Preparation of Tea.

The Board of Health of Kauagawa, Kem, have published a report, in which they condemn the preparation of tea as an unhealthy occupation. The dust arising from the process was one cause of danger, but the principal evil was found in the large proportion of carbonic acid in the atmosphere, amounting in the worst cases to as much as 2.73 parts per 1000 of air. This is caused by the charcoal fires used in the process, and its evil effects are very manifest in the livid appearance of the face and body of the worker.

"The Annals of Anatomy and Surgery."

The December issue of this journal closes its third year of existence. Though young, it is a remarkably vigorous production. Devoted to the subjects of anatomy and surgery, its advent filled a long existing void in medical journalism, and we trust it may have a long and prosperous future.

Items.

—The *Medical Summary* is much improved in the appearance of its cover.

—The State Sanitary Convention of New Jersey will meet at Trenton on the 14th and 15th of December.

—A man died recently in the Glasgow Infirmary, from hydrophobia resulting from the bite of a rabid dog on March 14th last.

—Dr. John A. Octerlony has been elected to the chair of Materia Medica, Therapeutics and Clinical Medicine in the University of Louisville.

—The family of a laborer, in San Francisco, were poisoned recently "by eating fish." Two children are dead, and another not expected to recover.

—The munificent legacy of $100,000 has been bequeathed to the Salop Infirmary, England, by the late Mr. Henry Spence, merchant, of Shrewsbury, who died recently.

—Dr. Alexander Ogston, Surgeon to the Aberdeen Royal Infirmary, has been appointed to the Chair of Surgery in the University of Aberdeen, in succession to Dr. Pirrie, who resigned some time ago.

—The following announcement was posted the other day in the Baltimore City Hospital: "If any gentleman has purchased a skeleton within the past few days he will confer a favor on Dr. Thomas by letting him know of whom he purchased it, for there has been one taken from the hospital. A reward will be paid and the gentleman allowed to keep the skeleton."

OBITUARY NOTICES.

DR. ALEXANDER N. DOUGHERTY,

a distinguished physician, and also a prominent local politician in Newark, New Jersey, died, Nov. 28th, of apoplexy, at the age of 60 years. He was a Corps Surgeon during the war, and is said to have attended General Hancock when he was wounded at Gettysburg.

DR. JOHN D. M. CARR,

a well-known physician, and one of the most advanced Masons in the United States, died recently, in Chicago, after a protracted illness.

DR. HUGO. KUENSTLER,

a German physician, well known in Harlem, who lived at No. 240 East One Hundred and Fifth street, died suddenly, on Sunday evening, Nov. 26th, while attending a patient. Dr. Kuenstler was 35 years of age and a native of Berlin. He had been in this country for eighteen years. He was graduated from the College of Physicians and Surgeons in 1871.

QUERIES AND REPLIES.

H. L. C., Groveport.—Such a case as you describe could not, with propriety, be termed "Pyæmia." A more correct designation would be "traumatic fever."

MARRIAGES.

BARHAM—NICHOLS.—At church, in Mt. Enterprise, Texas, by the Rev. J. S. Mathis, Sunday, Nov. 19th, 1882, Mrs. M. Nichols and S. H. Barham, M.D.

BRANNAN—DANA.—On Thursday, Nov. 9th, at the residence of the bride's parents, by the Rev. A. B. Hart, D.D., Dr. John Winters Brannan, of Colorado Springs, and Eunice, daughter of Charles A. Dana, of New York.

BULLOCK—ELLIS.—In Crosswicks, N. J., Nov. 5th, by Rev. A. G. Thomas, Lawrence M. Bullock, M.D., of Upland, and Miss Rebecca, daughter of the late Henry G. Ellis, of Crosswicks.

CROTHERS—CHRISTIE.—In West Nottingham, Md., October 25th, by Rev. S. A. Gayley, R. R. Crothers, M.D., and Fannie S. Christie, both of Rowlandsville, Md.

FROETZ—ROEDER.—On October 26th, 1882, at the residence of the bride's parents, by Rev. Dr. C. Z. Weiser, Dr. Oliver H. Fretz, of Salfordville, Montgomery county, and Miss Elmira N., eldest daughter of Nathan C. Roeder, of Spinnerstown, Bucks county, Pa.

JAMIESON—TRAPAGEN.—Wednesday, Nov. 8th, at Trinity Chapel, by Rev. Cornelius E. Swope, Dr. John Jamieson and Annie L. Trapagen, daughter of the late John E. Trapagen.

LATHAM—STRYKER.—On Wednesday, Nov. 15th, by the Rev. A. P. Stockwell, at the Reformed Church, Gravesend, Miss Frances M. Stryker and James R. Latham, M.D., of New York.

MARKLEY—PENROSE.—On Nov. 16th, at the Hotel Lafayette, in the presence of the Mayor of the city of Philadelphia, Dr. Arthur D. Markley, of Hatboro', Montgomery county, Pa., and Miss Hannah J. Penrose.

MILLIKIN—SCOTT.—On Thanksgiving day, Nov. 30th, 1882, at the residence of the bride's mother, by Rev. W. S. Danley, of Carmichaels, Pa., assisted by Rev. J. B. Baird, of Rice's Landing, Pa., John L. Millikin, M.D., of Carmichaels, Pa., foster son of W. S. Throckmorton, A.M., M.D., of Nineveh, Pa., and Miss Annie L. Scott, of Jefferson, Pa.

SMITH—BROWN.—On Tuesday, October 31st, by Rev. E. Greenwald, D.D., Amos H. Smith, M.D., of Paradise, Pa., and Ida Brown, of Harrisburg, Pa.

TAYLOR—SHARPLESS.—On Nov. 19th, by the Rev. Charles Morison, at the residence of the bride's mother, Edward Winslow Taylor, M.D., and Lillie H., daughter of the late Charles L. Sharpless.

WORKMAN—GRIMES.—On Thursday, November 2d, 1882, by Rev. J. G. Lyle, of Wheeling, W. Va., at the home of the bride's parents, Uniontown, O., John C. Workman, M.D., and Miss Jennie M. Grimes.

DEATHS.

MULFORD.—In the city of Camden, N. J., suddenly, on Nov. 21st, Isaac B. Mulford, M.D., in the 40th year of his age.

Smithsonian Institute

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts., **PHILADELPHIA.**

☞ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from $15 to $30, according to the number of currents. 1337-1351

CLINICAL STUDIES OF INEBRIETY—RATIONAL METHODS OF TREATMENT.

BY T. D. CROTHERS,

Superintendent of Walnut Lodge, Hartford, Conn.

In the rational treatment of inebriety, the first thing is the removal of all exciting causes. In a certain proportion of cases, alcohol is only a minor cause. It is an error to suppose that inebriety always depends upon the use of alcohol, and that its absolute removal will be followed by recovery.

The exciting causes which must be withdrawn are both complex and varied, only to be ascertained from a careful study of each case. In some instances these causes may be found in want of proper exercise, indigestion and irregularities of living, or in diseased conditions coming from overwork, underwork, or exhaustion from want of rest, sleep, etc. Many of these are physical, for instance, the sight of a man intoxicated, or stories of drinking, in which the pleasures and miseries are portrayed at length; or the efforts of a temperance lecturer, who in his attempts to alarm the hearer provokes the opposite feeling in an increased thirst for spirits. In my experience, extravagant descriptions of the sorrows from drink, and passionate appeals to stop, which is the burden of the reformed lectures, are often exciting causes and dangerous influences to a certain class of inebriates. On several occasions I have yielded to the entreaty of temperance people, and permitted lecturers to harangue my patients on the evils of inebriety, but always with bad results, invariably exciting, and in some cases stimulating, the old impulse to drink, perhaps by a reaction from the emotional excitement produced. Inebriates are always nerve exhausted and emotionally diseased; a reflex of the surroundings generally, feeling every change as keenly as the mercury responds to the state of the atmosphere. The exciting causes may be said to include everything which exhausts or unduly stimulates the weakened nervous system. The desire for alcohol is only an expression of this condition, which, from the experience of the patient, can be relieved only by spirits. These causes must be ascertained from a careful clinical study, and no permanent results can be expected unless the means of treatment are based on such knowledge. A common illustration is that of a man whose domestic relations are unhappy. His friends repeatedly upbraiding and scolding him for excesses in drink, threatening severe measures and means if he will not stop, and in this way rousing irritative emotions that react in cravings for spirits to relieve this feeling. Such cases find in the asylum freedom from these exciting causes, as well as abstinence from alcohol.

In another case, of a clerk who works, and is closely confined for many hours, living irregularly, eating, sleeping and using alcohol originally to quiet the protests of a starved organism. To him an asylum would be a relief from these irregularities, and the desire for alcohol dies out as these causes are removed. In both of these cases the surroundings of an asylum may be

greatly inferior to their accustomed homes, and possibly the removal from alcohol may not be absolute, and yet they recover, because the principal exciting causes are removed. If alcohol was the only exciting cause, the station house, the jail, or any room with locks and bars that would keep out spirits would be sufficient.

An asylum should be literally a quarantine, where every external exciting cause could be effectually taken away, and every condition of surroundings and circumstances that shall build up a healthy brain and nerve power gathered and applied.

If inebriety was a disease of some special organs, curative means might be found in certain remedies and particular forms of medication, which in a majority of cases would be successful. Experience shows that inebriety is the most complex of diseases, affecting all the organs of the body, requiring medication which influences the entire organism.

To effectually take away the exciting and predisposing influences, the patient must be placed in new surroundings, where all the mental and physical influences can be governed and controlled. The surroundings must be adapted to his special wants, where food, exercise, sleep, rest and enjoyment may be regulated so as to secure the greatest benefit from them.

Every hygienic means that shall build up the body and mind, together with medical skill, are requisite. These conditions cannot be obtained except in a special asylum or hospital, and no rational treatment will avail that dare not reach out to all the influences which enter into everyday life.

No home can furnish these means, however elegant it may be, and no insane hospital can bring freedom from all causes that are irritating; and no family physician can carry out a system of rational treatment that he does not direct personally, and have the power to enforce absolutely.

The exclusion of the exciting causes includes isolation from compounds of alcohol by a complete control over the patient, preventing him from procuring spirits when the impulse comes over him. In the case of a periodical inebriate, the return of the paroxysm may be retarded by the surroundings, and the body and mind built up so as to resist it, but it is certain to reappear, and the patient may be at the time more or less powerless to control the impulse.

If alcohol is accessible it will be used, and unless the patient is under control this cannot be prevented. Hence an institution must have legal power to restrain patients at times, preventing them from following the dictates of a diseased impulse, which grows gradually less and less, until it finally disappears. In a large majority of cases, this impulse is simply the reaction from certain states of exhaustion and debility, whose gratification may not impel them to great endeavors to procure it. As the rest and quiet of an asylum builds up healthy brain action, these reactions grow less, and are more easily controlled, and then, like the impulse of the periodic inebriate, die out.

Thus, the removal of existing causes must include all conditions which impel a man to drink, and all facilities to procure spirits while under treatment. This cannot be done in the centre of a city, in close proximity to places where spirits are sold, for the knowledge of this fact is often a predisposing cause to keep alive a thirst for spirits; nor can it be done where other active causes are not removed, as, for instance, excitement and exhaustion of any kind, want of proper food, rest, conditions of irritation, etc.

In every case of inebriety there is a definite physical cause, not always in alcohol, but in conditions which lead up to the constant use of spirits. Also, from the time of the first toxic action of alcohol there are special causes of exhaustion which may coöperate with or precipitate conditions of anæmia, instability and infirmity of the nerve element.

This state increases with the repetition of alcohol, and the combination of causes, growing further and further from the normal health standard. The rational cure can only come from definite physical change. This may be summarized in rest and proper nutrition of the nerve cell. The nerve cells of the mind centres are exhausted, and repair can only take place through rest. The blood must be improved, alcohol, of all other substances, destroys and perverts this function.

The shriveled appearance of the blood disks in the blood of inebriates proves that the organism is being starved and nutrition is broken up. Hence, special means, after the patient is quarantined from all exciting causes, in a proper asylum, are essential to improve the nutrition of the blood. Of these, iron, arsenic, cod-liver oil and milk (where it can be assimilated), are excellent. Food that will build up the tissue most rapidly should be given, particularly oatmeal, barley and rice, with wheat and corn, prepared in various ways; and fruits of nearly all kinds are found most useful. Of the various remedies that are given to build up the nerve and brain

force, the bitter barks, *nux vomica*, chlorate of potash, and phosphoric acid, are found by experience to be valuable. The electric current is, in a large proportion of cases, a decided tonic and stimulant; in others its effects are irritating, and its application is followed by a tumultuous excitement of the nerves and muscles that lasts a long time.

Sometimes these cases will only be benefited by the electric current in the latter stages of the treatment. This apparent idiosyncracy seems to pass away as the nerves grow stronger. In the first week of treatment this is not infrequent, and later, after a relapse, it may appear. The best results, in most cases, will probably be attained after one or two months of treatment; then the current should be applied along the spine every other day.

In some instances the sedative action of the current acts like a specific in cases where nervous agitation comes on from general causes, and grows gradually into an impulse for spirits. In the progress of the case under treatment many patients exhibit paroxysms of restlessness and general melancholy or irritability; sometimes these waves of mental and physical disturbance pass off in a short time, without provoking a desire for alcohol; in others the desire is present from the first, but is concealed, for the reason that the patient is either anxious to gratify or control it. These paroxysms are fortunately of short duration, and are succeeded by a period of calm and apparent full control, until finally they disappear.

Much skill and study is requisite in each case, to treat this condition or stage of the disease. To illustrate, a patient who has previously been quiet and in full accord with the physician in all efforts and means of treatment, will suddenly become suspicious and be greatly agitated over trifles, complain of restlessness, and inability to be quiet. He will eat and drink impulsively, either want large quantities of medicine or refuse to take any, and be confident that some other plan of treatment is necessary. The desire for drink will appear sooner or later, and all these diseased functional impulses seem to concentrate in that one direction, although the patient cannot realize its approach, and will be confident he will not use spirits. In some cases positive physical restraint at this time is injurious; in others, stimulating and quieting. The use of sedatives and narcotics, which seem to be indicated, vary greatly. Some forms of opium will cut off this paroxysm at once, or simply hold it in abeyance for a time, after which it breaks out with greater intensity. Belladonna and the vegetable narcotics are equally uncertain, and their physiological action is sometimes cumulative and long delayed. The bromides are more certain, yet they act often as simple checks for a time, followed by greater explosions. Where they are long continued, the paroxysm is worn out, apparently, and from debility it does not appear again. The electric current is more accurately a nerve sedative in many cases, than other remedies. Not unfrequently the most aggravated symptoms will disappear in an hour from the application of this means.

When these paroxysms occur at night, the patient is unable to sleep, and will walk the floor like a condemned prisoner, and should they last two or more days, some form of delirium, generally of suspicion and persecution, will appear. At such times the tact and skill of the physician is taxed to its utmost. Exercise is frequently suggested to the patient as the remedy, and like the drugs mentioned, it not unfrequently prolongs and intensifies the very condition it seeks to obviate.

The Turkish bath, like the electric current, is particularly valuable in a certain number of cases, and breaks up the paroxysm at once. In other cases it produces a sense of exhaustion that develops into a craving for spirits.

In one case the patient (an irregular inebriate), after a bath, becomes excessively hungry, and suffers from thirst; if he did not eat soon, he would have an intense desire for spirits, which would be very hard to restrain. In another case, when the paroxysm had developed into a sense of want of alcohol it would disappear as soon as the patient began to sweat in the hot room of the bath. The effects of moral treatment at this time are also variable and curious, from the variety of means, and the mysterious power they exercise. In an asylum where these periods can be studied carefully, and all the surroundings are controlled, mental impressions seem more powerful and lasting.

The influence of a letter from friends may either break up this period or provoke it. For instance, a wife writes to her husband of some trifling loss to herself or family, and the husband, a patient who has been resting cheerfully up to this time, begins to have the wildest apprehensions, and a tumultuous agitation, fearing the general failure of himself and all things. The condition, if not controlled, will end in an overpowering desire to drink again.

Medicine will not answer, but strong counteracting impressions and diversions are essential to

break up this state. Sometimes it is necessary to write to friends, and have them send the patients letters that will accomplish the purpose. Again, the diversion must come from the surroundings, by interesting the patient in some special work. Unlike an insane asylum, these moral and mental appliances for treatment must be positive, and interest the patient, either by their novelty and variety, appealing to every emotion, or through their intelligence, arousing a new train of thought and action. A large majority of patients, during the first three months of treatment, suffer frequently from these emotional disturbances or paroxysms, at intervals, and others are rarely free from them. The intervals between these periods are generally irregular, unless the patient is a periodical inebriate, or dipsomaniac, when they recur with great regularity. It has been found, without knowing why, that labor and occupation are essential, hence it has been urged by a class who know only in part, that the treatment cannot be successful unless this is the principal means. But in face of their assertions, hard labor in prison and close occupations do not heal or restore inebriates who are confined in such places. The fact is that occupation of mind and body, applied at certain times in the treatment of inebriety, is a veritable therapeutic measure, but its application is limited to particular conditions and times.

To make chair-bottoming or shoemaking the labor of an asylum, and force all inmates to engage in it, would be to fail in curative measures; or to go to the other extreme, and gather all patients into prayer meetings, appealing to their religious emotions two or three times a day, is equally certain to fail in a permanent cure. Occupation of mind and body is rationally all means which will prevent and break up these nerve paroxysms, and divert the mental and physical energies from exploding through these inebriate impulses. A few illustrations from every-day life in an asylum will explain this more clearly.

Case 1.—Is a periodic inebriate who every seven days has a period of intense sorrow and anxiety about his family. The treatment, besides small doses of bromide of sodium, consists in engaging his attention by driving out, giving him certain care and responsibility, enjoining on him the most minute directions as to exercise and baths. In twenty-four hours this passes away.

Case 2—Is an irregular inebriate who, from various causes, will become nervous and restless, and anxious to go back to business, although he has no business and no prospects of any kind. He will prepare and carry out the most elaborate schemes to go away, and be greatly agitated over them. After baths and the electric current (if not contra-indicated in the treatment) the mind can be diverted by examining the resources of Alaska or Central America, to find out the best prospect for business enterprise. In a few hours the agitation passes away and he is contented.

Case 3.—Is an irregular inebriate who becomes deeply engaged in the wrongs of others, and for several hours will go about seeking redress in the most hysterical manner, with much emotional excitement. If a patient has lately been admitted, and is suffering from what he thinks should be relieved by alcohol, he will espouse his cause and intrigue to procure spirits for him. The moral treatment consists of sharp reprimands and prompt, decisive commands to desist and look after his own interest. This, with remedial measures will suffice, and in a few hours he recovers.

No. 4—Is also an irregular inebriate, whose periods of nervous agitation disappear after a long walk.

No. 5—Is a similar case who recovers from some occupation of a few hours, as, for instance, working in the garden, arranging books in the library, or copying some article.

No. 6—Is a dipsomaniac who suffers every ten days from profound religious depression and agitation. The effort and excitement to write a temperance lecture will break up this depression. Brief religious service once a day, consisting largely of singing, in which all the patients may join, have a marked effect, not only to divert the mind, but to rouse up a new train of thought and feeling. Lectures, concerts, theatricals that are short and not exciting, have a strong influence and power in many cases. In these cases the study is to find subjects outside, upon which the mind may be concentrated and the energies of the body engrossed.

FRACTURE OF THE OS FEMORIS; ITS METHODS AND RESULTS.

BY E. MICHENER, M.D.,

Toughkenamon, Chester County, Pa.

I accepted the profession of medicine as a God-given trust, with feelings similar to those expressed by Dr. Winston (Reporter, Nov. 4th, p. 523), though perhaps with very inferior facilities. Under the growing infirmities of age, I have re-

leased myself, as far as practicable, from its responsibilities; but this does not absolve the obligations which I owe to the younger members of the profession, and to suffering humanity.

I was very early impressed with the incertitude of the teachings and the various methods employed in the treatment of fractures, especially the typical lesion of the shaft of the os femoris, which so often resulted in shortening and permanent lameness.

Under this impression, I devised a method of treating this fracture, which has proved entirely satisfactory and successful, during a period of more than sixty years. For a brief notice of this method, see MEDICAL AND SURGICAL REPORTER, Feb. 8th, 1881. See also, How Bones Break, etc., Nov. 19th, 1881.

Subsequently I brought the subject before the Medical Society of Chester County, for its consideration, who graciously appointed a committee of inquiry. A portion of the committee made me a courteous and acceptable visit. They referred me to Dr. Ashhurst, Professor of Clinical Surgery in the University of Pennsylvania, as a standard authority in such matters. Just where we should look for, and expect to find, the highest and noblest conception of practical and artistic skill in the treatment of this important lesion. But, so far as I know, the committee has failed to report the result of their inquiries. For

> "Who, that from Alpine heights, his laboring eye
> Shoots round the wide horizon, to survey
> Nilus, or Ganges, rolling his bright waves
> * * * * * * will turn his gaze
> To mark the windings of a scanty rill
> That murmurs at his feet?"

I accordingly reported my views to Prof. Ashhurst, emphasizing the facts—

1. That bones generally break dentated, the dentures readily interlocking, and holding the fragments in place.

2. That I had not found a fracture so oblique that the serrations would not hold the fragments in position when properly adjusted.

3. That I had never employed direct mechanical extension in the treatment of this fracture, and

4. That I had never discharged a patient with a shortened limb; or a limper.

To this I received the following kind and courteous reply:—

"DEAR DOCTOR: In reply to your very interesting letter, I would say that, in my experience, oblique fractures of the femur are more common than transverse fractures; and that I cannot recall more than a single case in which I have succeeded in curing a fracture of the thigh without shortening.

"Though, no doubt, most fractures are at first serrated, and this serration may, for a time, keep the fragments together, yet on the conversion of bone into granulation tissue, which precedes union, those serrations sometimes disappear, and hence consecutive shortening is very common.

"Very truly and respectfully yours,

"JOHN ASHHURST, JR."

I was grieved at this rebuff from such a source; a manifest indifference to the practical results which I had reported. But on taking up the REPORTER of 4th February last, I was delighted to see the announcement of a clinical lecture on fractures of the long bones, by Dr. Ashhurst, only to be again disappointed.

Now, standing at the portal of another world, I desire to make a hasty comparison of some of the methods and results of Dr. Ashhurst and myself.

There is shortening; you, therefore, need some means of extension. The older surgeons relied on the use of their hands, and upon splints, to maintain it; but in modern times the weight extension has been adopted. The method is now generally known as Buck's, or the American treatment.—*Dr. Ashhurst.*

I own to an "old surgeon," I greatly prefer a careful diagnosis, a skillful manipulation, and an accurate adjustment, and the retention of the fragments by appropriate dressings. These are of too much importance, in their immediate and ulterior results, to be delegated to the most ingenious combination of iron pulleys and weights.

Rather, let an assistant make the extension; very gentle at first, increasing it slowly, to avoid pain or exciting the femoral muscles to resistance. It may require five or ten minutes, an hour; no matter; don't be in a hurry. When the fragments are brought into a favorable position they are, in most cases, easily coapted. The dentures interlock, and the tonicity of the muscles holds them together. It is a rule, to which there should be few exceptions, that the bone should not be considered set until this result has been obtained.—*Dr. Michener.*

I do not suppose that we shall find much shortening in this case, as extension has been applied for forty-eight hours. We now have the patient squarely on his back. The right leg measures almost 34 inches; the left, not quite 33 inches.—*Dr. Ashhurst.*

Here appears to have been a disappointment. The limb was still an inch too short. So much to the credit of weight extension.—*Dr. Michener.*

We have applied here one brick. This afternoon we will add another, and, in the course of a week, a third. The weight should not, as a rule, exceed twelve pounds. What has become of Snowden's perfected apparatus? (REPORTER, April 2d, 1881.)—*Dr Ashhurst.*

I have already stated, and repeat the assurance, that I have for a long period treated patients with this fracture, from six months old

up to more than seventy years, successfully, without mechanical extension and without shortening. The question then arises, whether is it better to pursue the indefinite and uncertain method of machine extension, with all its horrors, or to reduce the fracture at once, and hold it so by appropriate dressings? Whether is the suffering or comfort of the patient worthy of the surgeon's notice?—*Dr. Michener.*

I have said indefinite and uncertain; I cannot recall more than a single case in which I succeeded in curing fracture of the thigh without shortening.—*Dr. Ashhurst.*

This shortening, if it does occur, from the conversion of the fracture facets into granulation tissues, and the subsequent condensation of the callus; is necesarily limited by the extent of the softening, is hardly appreciable; or what my friend Dr. Edw. Jackson has aptly termed, shortening without limping. I shall endeavor to show that no such retraction of the limb can take place under proper treatment.—*Dr. Michener.*

We need some support for the sides of the limb. I think that you will obtain better results from the use of these old fashioned, long splints—Physic's modification of Desault's apparatus. The outer splint should reach from the axilla to below the foot; the inner one from the groin to below the foot. We now secure the splints (rolled in a splint cloth), to the limb; padded with junk bags filled with bran. The splints are confined by five strips of bandage; one at the ankle, one at the knee, one below the groin, one at the crest of the ilium, and one around the chest.

When removed to the ward, we shall make counter extension by elevating the foot of the bed.

When the effusion in the knee-joint goes down, so that we can handle the joint without pain, we shall, at each dressing, if necessary, rotate the knee inwards, in order to overcome the tendency to eversion.—*Dr. Ashhurst.*

When, in the name of humanity, is this cruel, useless and meddlesome surgery, this tugging and twisting of the broken bone, to have an end?

It is no small matter to subject a patient to be thus pinioned down on his back for six or eight weeks, with a weight extension of twelve or more pounds, to be counteracted by making the bed an inclined plane and the head of the patient the most depending part. Does the partial success reported by Dr. Ashhurst warrant or excuse him to persist in such severe treatment, to the exclusion of milder means, which claim greater success?

In the case of children, from six months upward, I have always used an extemporized splint, made on the occasion, by cutting a shingle in two, and nailing them on an angular block. This simple fixture, with a bandage of strips, and a set of thigh splints, have fully met every indication.

For adults I use a more elaborate instrument, constructed more than sixty years ago. It is adaptable to all cases, and is always ready for use. Like the above it is virtually nothing more than an angular, concave, bed splint. (See Reporter, 8th Jan., 1881.) The minor thigh splints are important. They are formed of three strips of light wood, glued on a piece of muslin or thin leather. They should always embrace the whole length of the thigh, exclusive of the condyles. The padding should not exceed two or three smooth folds of soft flannel.

The dressing then reads, the angular bed splint, a strong bandage of strips, two lateral, and an upper thigh splint; the whole held by four unyielding leather bands, buckled tight around them. The foot may be supported, or left free, at the option of the patient, as the foot suspended over the angular splint has neither the tendency nor the power of eversion. This is only one of the many advantages derived from the angular position of the limb. I have never used any other. I prefer an angle of 35 or 40 degrees.—*Dr. Michener.*

You see, by this dressing, we fix the joints on both sides of the fracture. You may lay it down as a rule, *that in all fractures of the long bones, you must fix both the joint above and the one below the seat of fracture.—Dr. Ashhurst.*

I demur to this rule, as being erroneous in principle, and pernicious in practice.

It is self-evident that the long splint will rest upon the trochanter major and the external condyle. The inner one upon the internal condyle and in the groin, which is always intolerant of pressure. Thus the more important bone and surrounding tissues of the thigh are left without any more efficient support than bags of bran are capable of affording. And what is the result? The joints have been fixed; the fracture only partially so, if at all. The patient must, and will, seek relief by moving, so far as he can. Every motion extends to the injured limb and reacts upon the most movable part. And the joints being more stable than the broken bone, the reaction must inevitably fall upon it, as the point of least resistance.

I do, on the contrary, lay it down as a rule in this form of fracture, *the dressings should be exclusively applied to the injured thigh. Make its integrity complete by its own appliances, leaving the hip and knee joints free to respond to every movement of the body.*

Here, the whole extent of the femoral tissues are firmly grasped, and held together; muscular action is completely suspended; and any necessary or accidental motion reacts upon the free joints, leaving the intervening thigh to move in its entirety, without disturbance of the fracture. Hence the importance of an early and accurate adjustment of the fracture, before the dressings are applied.

Whatever appliances may be used, I believe that the secret of success lies in the skillful adjustment of the fracture; and a strict observance of the above rule in the application of the femoral dressings. Dress the injured member; not the man.—*Dr. Michener.*

It is not safe to allow the patient to walk in less than eight weeks. I remember a patient in the Pennsylvania Hospital, who had made

a good recovery [?] from fracture of the thigh, and was allowed to go about at the end of six weeks. There was at that time one fourth or one half an inch of shortening. After two or three days there was found two inches of shortening. At this time the callus uniting the bones is soft, and the pressure from walking readily causes consecutive shortening.—*Dr. Ashhurst.*

I have usually substituted light dressing, at the end of six weeks. But after the dressings which I used, the femoral muscles do not for some days recover power to use the limb in walking.

This extraordinary case seems to have been brought forward to illustrate what the lecturer considers to be the ordinary conversion of bone into granulation tissue. But it cannot belong to the same category with Dr. Jackson's cases of shortening without limping.

As a rebutter, I will recur to a case, already published (REPORTER, Nov. 19th, 1881, p. 567). A child of seven summers had her leg caught and dragged, under a log, on the public road. The soft parts of the upper anterior and inner tibial region were entirely torn away, the bones broken, the leg doubled back on the thigh, and the fragments all projecting. I noticed that the fractures were neither transverse nor oblique; they were dentated. After cutting off more than an inch of the upper tibial fragment, which was denuded of its periosteum, and left without any possible covering, I interlocked the dentated fragments of the fibula; and with the aid of a light lateral splint, and an angular splint underneath, rendered it an available stretcher to preserve the length of the limb, during the long period required for the cure. Notwithstanding the arduous duties imposed on this youthful fibula, there does not appear to have been softening, and consecutive shortening. There was, and is, no appreciable difference in the length of the limbs; nor the semblance of a limp. The subject of this narrative, a highly respected young lady, Mary Woodward, resides with her father, George Woodward, in Unionville, this county. Reference may be made.—*Dr. Michener.*

INHALATIONS OF ALCOHOL IN CROUPAL DIPHTHERIA.

BY DR. C. T. MELSHEIMER,

Bluffton, Ind.

Will the inhalations of alcohol cure croupal diphtheria, is the question that I wish to submit to your numerous readers, with a view of its solution by frequent trials in this exceedingly fatal disease. Some six weeks ago I was brought in contact with a typical case of this kind, and my former experience admonished me of the frailty of our present mode of medication, yet, as a matter of ease to my conscience, I gave the patient the benefit of the most approved treatment for some time, without deriving any benefit. The fact was, something more had to be done, and that something was nothing more than the inhalation of hot alcohol, by way of experiment. Under this treatment the patient made a good recovery, without the usual sequelæ that follow the graver forms of this disease, and were it not for a slight aphonia, her health is as good as it was before her marvelous escape from death. How much credit is due to this form of treatment I am not prepared to say, but my firm belief is that it was instrumental in saving her life. It may be possible that it had no effect whatever, and the recovery was simply due to one of those remarkable evolutions in nature that sometimes so unexpectedly comes to our relief in hopeless cases. Hence a more extensive trial will be necessary to determine the efficiency of this course of medication, etc.

On the 21st of October last I was summoned to visit Hattie Herbst, a resident of this place. Her mother reports her to be seven years old, and that she had been in good health prior to the 15th, when the exposure of a buggy ride through a "raw and chilly atmosphere produced a chill, followed by a mild fever. On the 16th she was well enough to attend school, and she continued so up to the afternoon of the 17th, when the return of another chill forced her to go home. On Wednesday, the 18th, her mother gave her several doses of quinine, which had the effect of abating the fever on the following day; but in the evening a hoarseness declared itself, with a dry, irritative cough, for which some kind of patent expectorant was given. Friday she appeared some better and continued so up to Saturday, when her cough and hoarseness progressively increased, and by night her cough had become croupal and her speech reduced to a mere whisper. This, in brief, is the history her mother gave, and the reason for not seeking medical aid sooner was that she made no special complaint of pain, or presented other symptoms of alarming illness until within a short time of my visit. I found her pale and anæmic-looking; skin dry, not very hot, with a temperature in the axilla of 99.30.° Head clear, senses intact; complains of pain in the left mastoid region. Countenance expressive of anxiety; yellow-coated tongue; a highly congested mucous membrane of the fauces and pharynx; enlarged tonsils, studded with irregular patches of dark gray deposit, forming parchment elevations that were surrounded with a border of dark red, which bled on the slightest touch. Perspiration stridulous and labored; croupal cough, with aphonia; no appetite, stomach irritable, bowels inclined

to constipation, urine partially suppressed, high colored, acid reaction, albuminous, and a specific gravity of 1.030; extremities cold; pulse 130 and very weak.

Now, if there is anything in the practice of medicine that is better calculated to humble the pride of a physician than a case of this kind, I have thus far failed to make the discovery, and I am very thankful for it. But we are called on to do something, and in our doing so we but demonstrate the impotency of our remedies and exhibit our ignorance of the cause to which they are directed for its removal. To be as consistent as possible with our imperfect knowledge of this disease, I prescribed stimulants in combination with iron, quinine, and chlorate of potash every three hours. Topical applications of tinct. iron and glycerin every four hours. Ordered the atmosphere of the room to be kept constantly moist by means of a large wash boiler of hot water, and in connection used inhalations of a five per cent. solution of carbolic acid every four hours, by means of a small antiseptic atomizer. This treatment was continued with variations in inhalation for some sixty hours without any improvement whatever; in fact, grew from bad to worse right along. There was a progressive increased difficulty of breathing, with spasms of the muscles of the glottis, that threatened a speedy death from asphyxia. Her countenance and extremities were purple. Pulse 160, thready and irregular, recession of the sternum and intercostal spaces with each inspiratory effort; she appeared to be beyond the relief of medicine, yet notwithstanding this hopeless condition I practiced the doctrine that as long as there was life there was hope. I abandoned all former treatment, with the exception of moist air, and resorted to the inhalations of hot alcohol, knowing that it would not compromise her condition in the least, and might possibly be the means of warding off death for a short time, at least; the alcohol used was rated at 88 per cent., and maintained at a temperature of 150° in the medicated cup. It was inhaled at a temperature of 120°, and reached the lungs through the nozzle of the atomizer, with a strength of about forty per cent. During the inhalation, which lasted about fifteen minutes, the pulse lost its intermittent character, and became somewhat fuller, the breathing more moist and less difficult. The paroxysms, that threatened speedy dissolution, were relieved, and a decided improvement for the better gave some hopes of recovery. The inhalations were kept up at regular intervals of two hours through the night, and by the following morning she presented every promise of returning health. The blueness of the face and extremities was disappearing, her breathing was much less difficult; she expectorated large quantities of flaky, membranous matter, had increased secretion from the kidneys, and improved appetite. To facilitate the expectoration a preparation of syr. senega, spts. nit. and sanguinarine, in sufficient doses for this purpose, was prescribed every three hours. This, in fact, embraces the only treatment, and with exception of a slight aphonia yet remaining, she is restored to health. At no time throughout the disease did the thermometer register more than 100°, with a low blood pressure, as was indicated by the character of the pulse. Her urine was scant; the eliminations from the kidneys seemed to hold a direct relation to the difficulty of breathing; at her worst period the amount of albuminous matter was equal by bulk to the urine.

Query.—What effect has the highly carbonated blood on the vaso-motor nerve? Does it become partially paralyzed to that extent that the peripheral zone of the renal capillaries becomes so weakened as to lose the power of resistance, and as a consequence, produce a passive interstitial congestion. I pause for a reply.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINICAL LECTURE BY WILLIAM PEPPER, M.D., LL.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

Lymphatic Pseudo-leucæmia.

Gentlemen:—Owing to my absence, I had not an opportunity of examining the patient from whom the specimens before us were removed.

I shall first read the history of this case, and then call attention to the results of the autopsy.

F. H., white; age 22 years; resident of Pennsylvania; a brakeman on the railroad by occupation. When ten years old, he began to work at picking slate, and from that time he has been much exposed to the weather. For the past two and a half years he has been employed as a brakeman. He used tobacco in every form, and coffee and alcohol (chiefly in the form of malt liquors) to excess. At the age of thirteen he had gonorrhœa, but denies ever having had syphilis. His parents are living and healthy; one sister has dropsy and another ophthalmia; another sister and two brothers are living and healthy. He has had whooping cough, but none of the specific diseases of childhood.

About the time that he had gonorrhœa, *i. e.*, nine years ago, he noticed enlargement of the glands under the right ear. These increased in

size, and gradually other glands became involved. All the tumors except one in front of the left ear were painless.

Six months ago urination increased in frequency, and the passage of the urine began to cause irritation. This became more marked until, when he was admitted to the hospital, he had to empty his bladder every five minutes.

About four months ago he began to feel a tingling, pricking pain in the lower extremities, extending from the crests of the ilia to the toes. He would occasionally, while urinating, feel a quick, darting sensation pass through the legs. During the past month the pricking pain extended above the iliac crest into the renal regions. The severity of the pain obliged him to quit work two and a half months ago.

Two months ago angeioleucitis, *i. e.*, inflammation of the lymphatic vessels and glands, developed in the left leg. This, apparently, was caused by the pressure of a large mass of glands upon the femoral vein and the lymphatics, as they pass through Scarpa's triangle. This condition remained for about a week.

He had lost some flesh, but with all his suffering, he had not become very much emaciated. He had lost strength, particularly during the past two or three months. He suffered from occasional hemorrhages, usually from the nose, but once from the bowel.

His condition at the time these notes were taken was as follows: "Hair brown; eyebrows and lashes black; the pupils of the eye contracted; face sallow; conjunctiva and sclerotic pearly and anæmic; the mucous membrane excessively pale." In other words, he presented all the evidences of a high degree of anæmia. The cervical and post-auricular glands enlarged; the smaller glands being round, smooth and painless, and the larger masses nodulated, and apparently made up of an aggregation of small glands. These were not freely movable. Only one of these masses (one in front of the left ear), was at all painful. At the vertex of the skull there was a ridge, running obliquely forward from right to left. This was firmly adherent to the tissues beneath.

Three years ago a gland was removed from the right side of the neck. The tumors were larger on the right side than on the left. The glands in the axillæ were enlarged. Both groins were affected, the left more than the right.

The left leg was white, œdematous, not painful; the skin tense, shining and cooler than on the opposite side. There was no œdema of the right leg. The tongue was red, flabby, fissured, but not coated. Appetite pretty good, and, except when he was indiscreet in his diet, he had no dyspepsia. The bowels were constipated and the stools dark in color. On percussion, the liver dullness was found to extend from the fourth rib to one and a half inches below the margin of the ribs. Hence there was considerable enlargement of the liver. On the left side a mass, dull on percussion, was found extending from the sixth rib above, to the level of the umbilicus below, and from the median line in front to the left lumbar region behind, where the dullness merged into that of the left kidney. This could scarcely be anything else but the spleen, greatly enlarged. The abdomen was tympanitic and without effusion.

The heart was pushed upward, the apex beating in the fourth interspace, in the line of the nipple. On auscultation, there was discovered a low-pitched, indistinct, blowing, systolic murmur, loudest at the apex and conducted into the axilla in the line of the apex. There was retraction of the apex with the systole of the heart; that is, at each beat of the heart the intercostal tissues at the apex were drawn in. The second sound was sharp. The aorta could be felt beating at the supra-sternal notch. The pulse was full and rather compressible.

Urination occurred every five minutes and was accompanied by severe pain. The urine was usually clear, but at times contained yellowish, stringy matter. The attempt to retain the urine caused great pain.

Before going further, let us consider the condition of the heart. Did the symptoms indicate disease of the heart? We have found that there was displacement of the heart, retraction of the tissues over the apex during the systole, and a low pitched murmur heard over the body of the heart and transmitted to the left. We cannot say that there has not been pericardial adhesions, which would cause retraction of the apex as the heart passed into systole; but the heart is so displaced and the normal relations of the parts so altered, that I should not attach the same importance to this sign in the present case, as I should if it were found with an enlarged heart and the liver and spleen about normal.

Does this murmur indicate mitral regurgitation? As you are aware, a murmur occupying the time of the systole of the heart, heard best at the apex and conducted to the left in line of the apex, is, under ordinary circumstances, pathognomonic of mitral regurgitation. Here, however, was a man intensely anæmic; when the crasis of the blood is so altered, it is thrown into vibration in its passage through the heart and blood vessels, and gives rise to a murmur. This is termed an anæmic or hæmic murmur. Such a murmur may have been present in this case, and have been conducted to the left through this large mass lying in contact with the heart, thus explaining the transmission of the anæmic murmur in that direction. Ordinarily, a hæmic murmur is not transmitted to the left, as its force is not sufficient to carry it through the spongy tissue of the lung. An organic murmur is carried to the left, because it is usually a murmur of greater penetrating force, and, in addition, is usually associated with alterations in the size and situation of the heart, which push away the lung tissue. From the history I should not definitely conclude that there is organic disease of the mitral value; even if there be a little disease of the mitral valve, it is clear that the intensely anæmic state of this man's blood would exaggerate any murmur produced there, and would explain in part its loud transmission to the left.

In regard to the urinary trouble. It is apparent, from the frequency of micturition and the character of the urine, that the condition could not be explained by mere acidity of the urine. There must have been chronic cystitis.

Finally, what are we to think of this curious, pricking pain which has been described as extending from the toes to the line of the ilium, and later, extending to the region of the kidney? I think this to have been due to the pressure of enlarged glands within the abdomen, upon the nerves emerging from the vertebral foramina, and passing into the legs.

I shall now complete the reading of the history.

The cremasteric and patellar reflexes were good. Sensation was diminished in the lower extremities. The line between normal and impaired sensibility corresponded to the crest of the ilium. There was loss of power over the lower extremities, *i. e.*, paraplegia; with this, dull pains in the calves of the legs, and darting pains and twitching in the lumbar region, were complained of. There was no sensation of chorda, *i. e.*, the feeling as though a cord were tied around the waist.

He was slightly hard of hearing in the left ear, but the other special senses were normal.

The urine was normal in quantity, with a specific gravity of 1.020. It contained neither albumen, nor sugar. The sediment consisted of amorphous and other phosphates, vesical epithelium, pus cells, but no casts, the absence of casts showing that the kidneys were not affected.

Sept. 5th. Œdema increasing.

Sept. 11th. The appetite began to fail, and there was dribbling of urine.

Sept. 12th. The blood was examined, and the proportion between the red and white corpuscles found to be normal.

Sept. 13th. The urine continued to dribble, the pain in the back still present. Temperature 100°. Continued to sink until he died, yesterday, Sept. 18th.

In considering these marked symptoms of paraplegia, etc., which I have just read for the first time, let us carefully study the condition of the spinal cord, as we have it from this relation of symptoms.

We here notice an interesting relation between the urinary symptoms and those belonging to the spinal cord. There are certain groups of cases where it is sometimes puzzling to determine which has been the primary trouble. A man who has had long continued irritation of the bladder gradually becomes paraplegic. In such a case we have to decide whether there has been a slow degenerative change in the antero-lateral columns (the motor columns) of the cord, gradually producing paraplegia and affecting the walls of the bladder (which are always affected when the paraplegia becomes at all complete), allowing the urine to remain in the bladder and undergo putrefactive changes, thus becoming a source of irritation, and producing cystitis; or whether, as a result of the long standing cystitis, the irritation has, by reflex influences, so acted upon the lumbar portion of the cord that its nutrition has been affected to such an extent that this portion of the cord passes into a state of anæmia, mal-nutrition, and possibly of softening. We have produced in this way reflex paraplegia, which may eventually be associated with organic changes in the cord.

The exact way in which the irritation of any extremity or surface gives rise to reflex paralysis is interesting and instructive, but a somewhat difficult subject for consideration. There are different views concerning it, but, in the first place, it is clear that the constant drain upon the nerve force of a section of the cord, which must occur where there is a constant irritation for months or years, must end by exhausting that centre. This may give rise to a functioual paralysis. An examination of the cord may reveal no signs of organic disease.

Again, you can readily understand that as the vessels of any part are influenced by nervous action, and that as distant irritation is able to cause spasmodic contraction of these vessels, a long continued irritation may cause such a continuous contraction of the blood vessels of a segment of the cord, so impairing its nutrition, that it may pass into a state of slow degeneration and passive softening. In the present case the urinary irritation had certainly lasted sufficiently long to produce reflex paraplegia. But urinary irritation was not the only trouble this man had. There were masses of enlarged glands externally, and in all probability internally also. I have no doubt we shall find the glands along the spinal column enlarged. Here, then, might be another explanation of the paraplegia: direct pressure upon the nerves emerging through the vertebral foramina; not only so, but the enlarged glands may have extended through the foramina, and actually pressed upon the substance of the cord. These possibilities must be considered. What do we learn from a study of the patellar and cremasteric reflexes? These were well marked. The reflex from tickling the sole of the foot was also present. These reflex phenomena are impaired when the posterior columns of the spinal cord suffer from organic disease; but they remain and may indeed be excessive in cases where the lateral or the antero-lateral columns are the seat of disease. You have heard that sensation was impaired. This would point to a lesion affecting the posterior columns of the cord. So that it is not improbable that we had in addition to the reflex paralysis (which we might expect to find from the long continued cystic irritation), an encroachment of these enlarged glands upon the nerve cords or on the spinal cord, or even actual changes in the spinal cord.

This is an exceedingly complicated and interesting case, and we are at a great disadvantage in having only the post-mortem record from which to study it.

What was the matter with this man? We have considered the vesical and the nervous trouble, but neither of these was the primary trouble. The initial disease was a progressive hypertrophy of the lymphatic glands, and eventually enlargement of the liver and spleen. We find enlargement of the lymphatic glands in syphilis, cancer and scrofulosis. We also find it where none of these diseases exist, and where it apparently constitutes the whole disease. The patient sinks into a condition of anæmia; the exhaustion increases, and he dies. After death the lesions are those of a curious overgrowth of the lymphatic structures.

Had this young man cancer? Primary cancer
